

# 36V, 2A, Configurable-Frequency, Low-IQ, Synchronous Step-Down Converter with 42V Load Dump Tolerance

### DESCRIPTION

The MP4322 is a configurable-frequency (350kHz to 2.5MHz), synchronous, step-down switching converter with integrated internal high-side and low-side power MOSFETs (HS-FET and LS-FET, respectively). The device provides up to 2A of highly efficient output current (I<sub>OUT</sub>) with peak current mode control.

The wide 3.3V to 36V input voltage ( $V_{IN}$ ) range and 42V load dump tolerance accommodates a variety of step-down applications in automotive input environments. A 1 $\mu$ A shutdown current ( $I_{SD}$ ) allows the device to be used in battery-powered applications.

High power conversion efficiency across the entire load range is achieved by scaling down the switching frequency (f<sub>SW</sub>) under light-load conditions to reduce switching and gate driver losses.

An open drain power good (PG) signal indicates whether the output is within 94.5% to 105.5% of its nominal voltage.

Frequency foldback prevents inductor current  $(I_L)$  runaway during start-up. Thermal shutdown provides reliable, fault-tolerant operation.

High duty cycle and low-dropout (LDO) mode are provided for automotive cold-crank conditions.

The MP4322 is available in a QFN-12 (2mmx3mm) package with wettable flanks.

### **FEATURES**

- Designed for Aftermarket Automotive Applications:
  - 42V Load Dump Tolerance
  - Supports 3.1V for Cold Crank Conditions
  - o Up to 2A of Continuous Output Current
  - Continuous Operation Up to 36V
  - -40°C to +125°C Junction Temperature (T<sub>J</sub>) Range

### FEATURES (continued)

- Increases Battery Life:
  - 1µA Shutdown Supply Current (I<sub>SD</sub>)
  - 20μA Sleep Mode Quiescent Current (I<sub>Q</sub>)
  - Advanced Asynchronous Modulation (AAM) Mode Increases Efficiency under Light Loads
- High Performance for Improved Thermals:
  - o Integrated 70m $\Omega$ /50m $\Omega$  MOSFETs
  - 65ns Minimum On Time (t<sub>ON\_MIN</sub>)
  - 50ns Minimum Off Time (t<sub>OFF MIN</sub>)
- Optimized for EMC/EMI:
  - Frequency Spread Spectrum (FSS) Modulation
  - o Symmetric VIN Pinout
  - o CISPR25 Class 5 Compliant
  - 350kHz to 2.5MHz Configurable Switching Frequency (f<sub>SW</sub>)
  - MeshConnect<sup>™</sup> Flip-Chip Package
- Additional Features:
  - Power Good (PG) Output
  - Low-Dropout (LDO) Mode
  - Fixed Output Options <sup>(1)</sup>: 1V, 1.8V, 2.5V, 3.0V, 3.3V, 3.8V, 5V
  - Hiccup Over-Current Protection (OCP)
  - Available in a QFN-12 (2mmx3mm)
     Package
  - Available in a Wettable Flank Package

### **APPLICATIONS**

- USB Chargers
- Aftermarket Automotive Applications
- Battery-Powered Systems
- General Consumer Applications

#### Note:

 See the Ordering Information section on page 3 for details regarding the fixed-output versions. Additional output voltages may be available. Contact MPS for details.

All MPS parts are lead-free, halogen-free, and adhere to the RoHS directive. For MPS green status, please visit the MPS website under Quality Assurance. "MPS", the MPS logo, and "Simple, Easy Solutions" are trademarks of Monolithic Power Systems, Inc. or its subsidiaries.

### **PACKAGE REFERENCE**

## **PIN FUNCTIONS**

Pin#	Name	Description
1, 11	PGND	Power ground.
2, 10	VIN	<b>Input supply.</b> The VIN pins supply power to the internal control circuitry and the power MOSFET connected to the SW pin. The two VIN pins are connected internally. Place a decoupling capacitor connected to PGND as close as possible to each VIN pin to minimize switching spikes.
3	воот	<b>Bootstrap.</b> The BOOT pin is the positive power supply for the high-side MOSFET (HS-FET) driver connected to SW. Connect a bypass capacitor between the BOOT and SW pins.
4	FREQ	<b>Switching frequency configuration.</b> Connect a resistor between the FREQ pin and AGND to set the switching frequency (f <sub>SW</sub> ).
5	VCC	<b>Bias supply.</b> The VCC pin is the output of the internal regulator that supplies power to the internal control circuitry and gate drivers. Place a >1µF decoupling capacitor between VCC and AGND.
6	AGND	Analog ground.
7	FB	<b>Feedback input.</b> The FB pin is the negative input of the error amplifier (EA) (typically 0.8V). For the fixed-output versions, connect FB directly to the output voltage (V <sub>OUT</sub> ). For the adjustable-output version, connect FB to the middle point of the external feedback divider between the output and AGND to set V <sub>OUT</sub> .
8	PG	<b>Power good output.</b> The PG pin is an open-drain output. If PG is used, connect PG to a power source via a pull-up resistor. If V <sub>OUT</sub> is within 94.5% to 105.5% of the nominal voltage, then PG goes high. If V <sub>OUT</sub> exceeds 107% or drops below 93% of the nominal voltage, then PG goes low. Float PG if not used.
9	EN	<b>Enable.</b> Pull EN above 1.02V to turn the converter on; pull the EN pin below 0.85V to turn it off. EN does not require an internal pull-up or pull-down resistor. Do not float EN.
12	SW	<b>Switch node.</b> The SW pin is the source of the HS-FET and the drain of the low-side MOSFET (LS-FET).

#### Notes:

- Absolute maximum ratings are rated under room temperature, unless otherwise noted. Exceeding these ratings may damage the device.
- 4) Refer to ISO16750.
- 5) The maximum allowable power dissipation is a function of the maximum junction temperature  $T_J$  (MAX), the junction-to-ambient thermal resistance  $\theta_{JA}$ , and the ambient temperature  $T_A$ . The maximum allowable continuous power dissipation at any ambient temperature is calculated by  $P_D$  (MAX) =  $(T_J$  (MAX)  $T_A$ ) /  $\theta_{JA}$ . Exceeding the maximum allowable power dissipation can cause excessive die temperature, and the regulator may go into thermal shutdown. Internal thermal shutdown circuitry protects the device from permanent damage.
- Per ANSI/ESDA/JEDEC JS-001.
- 7) Per ANSI/ESDA/JEDEC JS-002.
- 8) The device may be able to operate at junction temperatures above 125°C. Contact an MPS FAE for more details.
- 9) Measured on a JESD51-7, 4-layer PCB. The values given in this table are only valid for comparison with other packages and cannot be used for design purposes. These values were calculated in accordance with JESD51-7, and simulated on a specified JEDEC board. They do not represent the performance obtained in an actual application, the value of  $\theta_{\rm JC}$  shows the thermal resistance from junction-to-case bottom, and the value of  $\Psi_{\rm JT}$  shows the characterization parameter from junction-to-case top.
- 10) Measured on the MPS MP4322GDE standard EVB: 8.3cmx8.3cm, 2oz copper thickness, 4-layer PCB. The value of  $\Psi_{JT}$  shows the characterization parameter from junction-to-case top.

## **FUNCTIONAL BLOCK DIAGRAM**

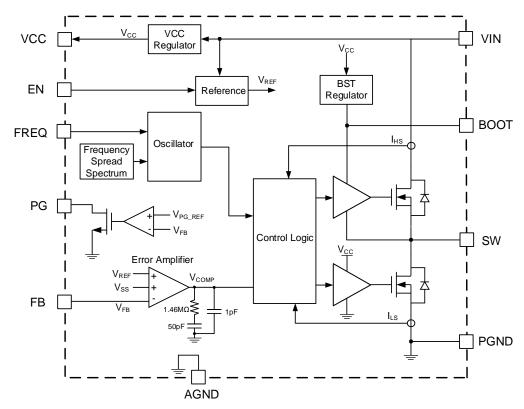

Figure 3: Functional Block Diagram (Adjustable-Output Version)

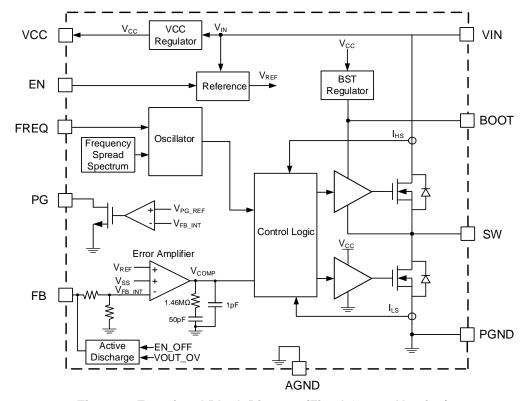

Figure 4: Functional Block Diagram (Fixed-Output Version)

## **OPERATION**

The MP4322 is a synchronous, step-down switching converter with integrated internal high-side and low-side power MOSFETs (HS-FET and LS-FET, respectively). It can achieve up to 2A of highly efficient current (I<sub>OUT</sub>) with peak current mode control.

The device features a wide input voltage ( $V_{IN}$ ) range, 350kHz to 2.5MHz configurable switching frequency ( $f_{SW}$ ), internal soft start (SS), and precise current limiting. The MP4322's low operational quiescent current ( $I_Q$ ) makes it well-suited for battery-powered applications.

### **Pulse-Width Modulation (PWM) Control**

At moderate to high output currents, the MP4322 operates with a fixed frequency, peak current mode control to regulate the output voltage  $(V_{OUT})$ . A PWM cycle is initiated by the internal clock. At the rising edge of the clock, the HS-FET turns on and remains on until the control signal reaches the value set by the internal COMP voltage  $(V_{COMP})$ .

When the HS-FET is off, then the LS-FET turns on and remains on until the next cycle starts or until the inductor current ( $I_L$ ) drops below the zero-current detection (ZCD) threshold. The LS-FET remains off for at least the minimum off time ( $t_{OFF\_MIN}$ ) before the next cycle starts.

If the current in the HS-FET cannot reach the value set by  $V_{\text{COMP}}$  within one PWM period, then the HS-FET remains on and skips a turn-off operation. The HS-FET is forced off once it reaches the value set by  $V_{\text{COMP}}$ , or once its maximum on time  $(t_{\text{ON\_MAX}})$   $(7\mu s)$  is complete. This mode extends the duty cycle, which achieves low dropout while  $V_{\text{IN}} \approx V_{\text{OUT}}$ .

### **Light-Load Operation**

The MP4322 operates in advanced asynchronous modulation (AAM) mode to optimize efficiency under light-load and no-load conditions.

The MP4322 enters asynchronous operation as the inductor current ( $I_L$ ) approaches 0A under light-load conditions. If the load decreases further,  $V_{COMP}$  drops to its set value, and the device enters AAM mode (see Figure 5).

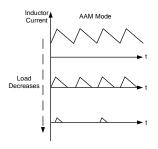

Figure 5: AAM Mode

In AAM mode, the internal clock is resets once  $V_{\text{COMP}}$  reaches its set value. The crossover time is used as a benchmark for the next clock. If the load increases and  $V_{\text{COMP}}$  exceeds its set value, then the device operates in continuous conduction mode (CCM) or discontinuous conduction mode (DCM) with a constant  $f_{\text{SW}}$ .

## **Error Amplifier (EA)**

The error amplifier (EA) compares the feedback (FB) voltage ( $V_{FB}$ ) to the internal reference voltage ( $V_{REF}$ ) (typically 0.8V), and outputs a current proportional to the difference between the two voltages. This current charges the compensation network to set  $V_{COMP}$ , which controls the power MOSFET's duty cycle.

During normal operation, the minimum  $V_{\text{COMP}}$  is clamped to 0.5V, and the maximum is clamped to 2V. If the IC shuts down,  $V_{\text{COMP}}$  is pulled down to AGND internally.

### Frequency Spread Spectrum (FSS)

The MP4322 employs a 15kHz modulation frequency and a 128-step triangular profile to spread the internal  $f_{SW}$  across a 20% (±10%) window. The steps vary with the  $f_{SW}$  to ensure that the exact  $f_{SW}$  steps cycle by cycle (see Figure 6).

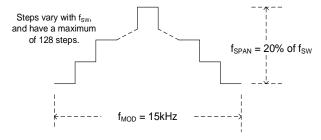

Figure 6: Frequency Spread Spectrum

Sidebands are created by modulating  $f_{SW}$  via the triangle modulation waveform. The emission power of the fundamental  $f_{SW}$  and its harmonics are distributed into smaller portions. This significantly reduces peak EMI noise.

### Soft Start (SS)

Soft start (SS) is implemented to prevent  $V_{\text{OUT}}$  from overshooting during start-up. The soft-start time ( $t_{\text{SS}}$ ) is fixed internally.

Once SS is initiated, the soft-start voltage ( $V_{SS}$ ) rises from 0V to 1.2V with a set slew rate. If  $V_{SS}$  drops below the internal  $V_{REF}$  (0.8V), then  $V_{SS}$  takes over and the EA uses  $V_{SS}$  as its reference. If  $V_{SS}$  exceeds  $V_{REF}$ , the EA uses  $V_{REF}$  as its reference.

During start-up through EN, the first pulse occurs after about  $830\mu s$ . During this period, the VCC voltage (V<sub>CC</sub>) is regulated, the internal bias is generated, and the compensation network is charged. After another 2.9ms, V<sub>OUT</sub> ramps up and reaches its set value. SS is complete after another 1.5ms. PG is also pulled high after a 70 $\mu s$  delay.

### **Pre-Biased Start-Up**

If  $V_{FB}$  exceeds  $V_{SS}$  during start-up, this means that the output has a pre-biased voltage. Both the HS-FET and LS-FET remain off until  $V_{SS}$  exceeds  $V_{FB}$ .

#### Thermal Shutdown

Thermal shutdown prevents the device from operating at exceedingly high temperatures and protects it from thermal runaway. If the die temperature exceeds its upper threshold (about 175°C), the device shuts down. Once the temperature drops below 155°C, the device restarts and resumes normal operation.

### Start-Up and Shutdown

If both  $V_{\text{IN}}$  and the EN voltage ( $V_{\text{EN}}$ ) exceed their respective thresholds, the IC starts up. The reference block starts up first to generate a stable  $V_{\text{REF}}$  and reference currents. Then the internal regulator is enabled to provide a stable supply for the remaining circuitries.

Once the internal supply rail is up, the internal circuits begin operating. If the BOOT voltage ( $V_{BOOT}$ ) does not reach its refresh rising threshold (about 2.5V), then the LS-FET turns on to charge BOOT. The HS-FET remains off during this charging period. When the soft start block is enabled,  $V_{OUT}$  starts to ramp up slowly and smoothly until it reaches its target voltage.  $V_{OUT}$  should reach its target voltage within 5ms.

Three events can shut down the chip: EN going low,  $V_{\text{IN}}$  falling below its UVLO threshold, and thermal shutdown. During shutdown, the signaling path is blocked to avoid any fault triggering. Then  $V_{\text{COMP}}$  is pulled down and the floating driver disabled the HS-FET.

# **APPLICATION INFORMATION**

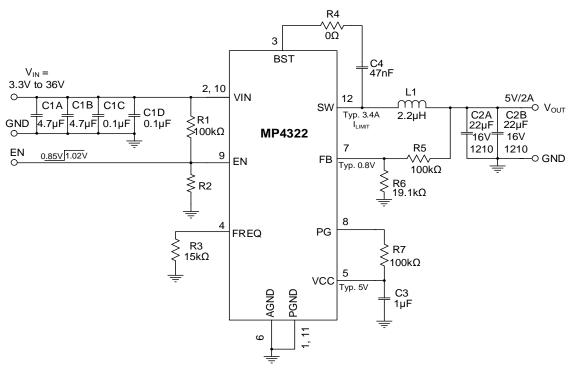

Figure 7: Typical Application Circuit ( $V_{OUT} = 5V$ ,  $f_{SW} = 2.2MHz$ )

### GND Connection (Pins 1, 6, and 11)

See the PCB Layout Guidelines section on page 35 for more details.

# Selecting the Input Capacitors (VIN, Pins 2 and 10)

The step-down converter has a discontinuous input current ( $I_{\text{IN}}$ ), and requires a capacitor to supply AC current to the converter while maintaining the DC  $V_{\text{IN}}$ . Use low-ESR capacitors for the best performance. Ceramic capacitors with X5R or X7R dielectrics are recommended due to their low ESR and small temperature coefficients.

For most applications, a  $4.7\mu F$  to  $10\mu F$  capacitor is sufficient. It is strongly recommended to use an additional, lower-value capacitor (e.g.  $0.1\mu F$ ) with a small package size (e.g. 0603) to absorb high-frequency switching noise. Place the smaller capacitor as close to VIN and PGND as possible.

Since the input capacitor ( $C_{IN}$ ) absorbs the input switching current, it requires an adequate ripple current rating. The RMS current in  $C_{IN}$  ( $I_{CIN}$ ) can be estimated with Equation (1):

$$I_{CIN} = I_{LOAD} \times \sqrt{\frac{V_{OUT}}{V_{IN}} \times (1 - \frac{V_{OUT}}{V_{IN}})}$$
 (1)

The worst-case condition occurs at  $V_{IN} = 2 x V_{OUT}$ , which can be calculated with Equation (2):

$$I_{CIN} = \frac{I_{LOAD}}{2}$$
 (2)

For simplification, choose an input capacitor with an RMS current rating greater than half of the maximum load current ( $I_{LOAD\_MAX}$ ).  $C_{IN}$  can be electrolytic, tantalum, or ceramic. When using electrolytic or tantalum capacitors, add a small, high-quality ceramic capacitor (e.g.  $0.1\mu F$ ) as close to the IC as possible. When using ceramic capacitors, ensure that they have enough capacitance to provide a sufficient charge to prevent excessive voltage ripple at the input. The input voltage ripple ( $\Delta V_{IN}$ ) caused by the capacitance can be estimated with Equation (3):

$$\Delta V_{IN} = \frac{I_{LOAD}}{f_{SW} \times C_{IN}} \times \frac{V_{OUT}}{V_{IN}} \times (1 - \frac{V_{OUT}}{V_{IN}})$$
 (3)

# Floating Driver and Bootstrap Charging (BOOT, Pin 3)

The bootstrap capacitor (C4, also called  $C_{\text{BOOT}}$ ) is recommended to be between 22nF and 100nF.

It is not recommended to place a resistor ( $R_{BOOT}$ ) in series with  $C_{BOOT}$ , unless there is a strict EMI requirement.  $R_{BOOT}$  reduces EMI and voltage stress at high input voltages; however, it also generates additional power consumption and reduces efficiency. If necessary,  $R_{BOOT}$  should be less than  $4\Omega$ .

The voltage between the BOOT and SW pins  $(V_{BOOT-SW})$  is regulated to about 5V by the dedicated internal bootstrap regulator. If  $V_{BOOT-SW}$  drops below its regulated value, then an N-channel MOSFET pass transistor connected between VCC and BOOT turns on to charge  $C_{BOOT}$ . The external circuit should provide enough voltage headroom to facilitate charging.

When the HS-FET is on,  $V_{BOOT}$  is higher than  $V_{CC}$ , so  $C_{BOOT}$  cannot charge. At higher duty cycle operation, the time available for bootstrap charging is shorter, so the bootstrap capacitor may not charge sufficiently. If the external circuit has an insufficient voltage and time to charge  $C_{BOOT}$ , extra external circuitry can be used to ensure that  $V_{BOOT}$  remains within its normal operating range.

If  $V_{BOOT}$  falls below its UVLO threshold, then the HS-FET turns off and the LS-FET turns on for  $t_{OFF\ MIN}$  to refresh  $V_{BOOT}$  via the set  $f_{SW}$ .

# Setting the Switching Frequency (FREQ, Pin 4)

A frequency resistor (R3, also called  $R_{\text{FREQ}}$ ) can be used to set the MP4322's internal switching frequency ( $f_{\text{SW}}$ ) (see Table 2 on page 32 and the  $f_{\text{SW}}$  vs.  $R_{\text{FREQ}}$  curves on page 16).

Place  $R_{FREQ}$  between the FREQ pin and AGND, as close as possible to the IC.

Since the MP4322 works in advanced asynchronous modulation (AAM) mode to optimize efficiency under light loads, its real  $f_{SW}$  also depends on the depth of its AAM mode. The AAM mode depth is related to inductance and load. The curves on Page 16 shows the detail relationship between  $f_{SW}$  vs.  $R_{FREQ}$  under

different loads and inductances. When the load is  $\geq 1A$ , the real switching frequency is equal to the set  $f_{SW}$ .

Table 2 shows the recommended resistances for different switching frequencies.

Table 2: fsw vs. RFREQ

R <sub>FREQ</sub> (kΩ)	f <sub>sw</sub> (kHz)	R <sub>FREQ</sub> (kΩ)	f <sub>SW</sub> (kHz)
100	355	30.1	1150
93.1	385	26.1	1300
86.6	415	22.6	1450
80.6	450	20.5	1600
75	480	19.6	1750
68.1	520	17.8	1900
59	600	16.2	2050
51.1	700	15	2200
40.2	850	14.3	2350
34.8	1000	13.3	2500

It is not possible to have both a high  $f_{SW}$  and a high  $V_{IN}$  due to the HS-FET's limited minimum on time  $(t_{ON\_MIN})$ . The MP4322's control loop automatically sets the maximum possible  $f_{SW}$  to the set frequency, which also reduces excessive power loss.  $V_{OUT}$  is regulated by varying the duration of the HS-FET's off time, which reduces  $f_{SW}$ .

The device is guaranteed to adhere to the HS-FET's  $t_{ON\_MIN}$ . An advantage of this method is that the device operates at the target  $f_{SW}$  for as long as possible, and  $f_{SW}$  only changes when the device operates at high input voltages. For more details, see the  $f_{SW}$  vs.  $V_{IN}$  curve on page 16, where  $R_{FREQ} = 15k\Omega$ ,  $V_{OUT} = 3.3V$ , and  $I_{OUT} = 3A$ .

### Internal VCC (VCC, Pin 5)

The VCC capacitance is recommended to be  $1\mu F$ .

Most of the internal circuitry is powered by the internal, 5V VCC regulator. This regulator uses  $V_{\text{IN}}$  as its input and operates across the entire  $V_{\text{IN}}$  range. If  $V_{\text{IN}}$  exceeds 5V, then  $V_{\text{CC}}$  is in full regulation. If  $V_{\text{IN}}$  drops below 5V, then the VCC output degrades.

### Feedback (FB, Pin 7)

For the adjustable-output version, the typical feedback voltage ( $V_{FB}$ ) is 0.8V. The external resistor dividers (R6 and R5) connected to FB sets  $V_{OUT}$  (see Figure 8).

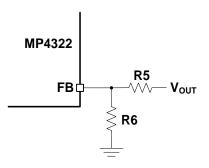

Figure 8: Feedback Divider Network for Adjustable-Output Version

Calculate the value of R6 with Equation (4):

$$R_6 = \frac{R_5}{\frac{V_{OUT}}{0.8V} - 1}$$
 (4)

For the fixed-output version, the FB resistor dividers ( $R_{FB1}$  and  $R_{FB2}$ ) are integrated internally (see Figure 9). Connect FB directly to  $V_{OUT}$  to set the output voltage. The following fixed outputs can be selected: 1V, 1.8V, 2.5V, 3V, 3.3V, 3.8V, 5V.

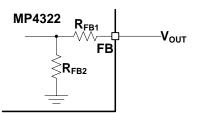

Figure 9: Feedback Divider Network for Fixed-Output Version

Table 3 shows the relationship between the internal  $R_{\text{FB}}$  and  $V_{\text{OUT}}$ .

Table 3: RFB vs. Vout

V <sub>оит</sub> (V)	R <sub>FB1</sub> (kΩ)	R <sub>FB2</sub> (kΩ)
1	64	256
1.8	320	256
2.5	544	256
3.0	704	256
3.3	800	256
3.8	960	256
5	1344	256

### Power Good (PG) Indicator (PG, Pin 8)

The PG resistor (R7, also called  $R_{PG}$ ) should have a resistance of about  $100k\Omega$ .

The MP4322 includes an open-drain power good output (PG) that indicates whether  $V_{\text{OUT}}$  is within its nominal range.

4/6/2023

If using PG, connect it to a logic high power source (e.g. 3.3V) via a pull-up resistor. If  $V_{\text{OUT}}$  is within 94.5% to 105.5% of the nominal voltage, PG goes high. if  $V_{\text{OUT}}$  is above 107% or below 93% of the nominal voltage, PG goes low. Float PG if it is not used.

# Enable and Under-Voltage Lockout (UVLO) (EN, Pin 9)

The EN pin is a digital control pin that turns the converter on and off.

# Enabled by an External Logic High/Low Signal

If the EN voltage ( $V_{EN}$ ) reaches 0.7V, the bottom gate (BG) does not turn on until  $V_{IN}$  exceeds 2.7V. BG then provides an accurate reference voltage for the EN threshold. Pull EN above its rising threshold (about 1.02V) to enable the device. Pull EN below 0.85V to shut down the device. There is no internal pull-up or pull-down resistor connected to the EN pin. Do not float EN. If the control signal cannot give an accurate high or low logic, then an external pull-up or pull-down resistor is required.

# Configurable V<sub>IN</sub> Under-Voltage Lockout (UVLO) Threshold

The MP4322 has an internal, fixed under-voltage lockout (UVLO) threshold. The rising threshold is 3.65V, and the falling threshold is about 2.9V. For applications that require a higher UVLO, place an external resistor divider between VIN and EN to raise the equivalent UVLO threshold (see Figure 10).

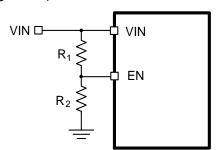

Figure 10: Configurable UVLO via the EN Divider

The UVLO rising threshold (V<sub>IN\_UVLO\_RISING</sub>) can be calculated with Equation (5):

$$V_{\text{IN\_UVLO\_RISING}} = \left(1 + \frac{R_1}{R_2}\right) \times V_{\text{EN\_RISING}}$$
 (5)

Where  $V_{EN\ RISING}$  is 1.02V.

The UVLO falling threshold (V<sub>IN\_UVLO\_FALLNG</sub>) can be calculated with Equation (6):

$$V_{IN\_UVLO\_FALLING} = (1 + \frac{R_1}{R_2}) \times V_{EN\_FALLING}$$
 (6)

Where V<sub>FN</sub> FALLING is 0.85V.

If EN is not used to turn the IC on and off, connect EN to a high-voltage source (e.g. VIN) to turn the device on by default.

### Selecting the Inductor (SW, Pin 12)

The inductance (L) can be estimated with Equation (7):

$$L = \frac{V_{OUT}}{f_{SW} \times \Delta I_{L}} \times (1 - \frac{V_{OUT}}{V_{IN}})$$
 (7)

Where  $\Delta I_{L}$  is the peak-to-peak inductor ripple current.

A 1µH to 10µH inductor with a DC current rating at least 25% higher than the maximum load current is recommended for most applications. For higher efficiency, choose an inductor with a lower DC resistance. A larger-value inductor results in less ripple current and a lower output ripple voltage; however, it also has a larger physical size, higher series resistance, and lower saturation current. A good rule for determining the inductance is to allow the inductor ripple current to be approximately 30% of the maximum load current.

The peak inductor current ( $I_{L\_PEAK}$ ) can be calculated with Equation (8):

$$I_{L_{-PEAK}} = I_{LOAD} + \frac{V_{OUT}}{2 \times f_{SW} \times L} \times (1 - \frac{V_{OUT}}{V_{IN}})$$
 (8)

Choose an inductor that does not saturate under  $I_{L\ PEAK}$ .

The output voltage ripple  $(\Delta V_{OUT})$  can be estimated with Equation (9):

$$\Delta V_{\text{OUT}} = \frac{V_{\text{OUT}}}{f_{\text{SW}} \times L} \times (1 - \frac{V_{\text{OUT}}}{V_{\text{IN}}}) \times (R_{\text{ESR}} + \frac{1}{8 \times f_{\text{SW}} \times C_{\text{OUT}}}) \quad (9)$$

Where L is the inductance, and  $R_{ESR}$  is the equivalent series resistance (ESR) of the output capacitor ( $C_{OUT}$ ).

### **Selecting the Output Capacitors (SW, Pin 12)**

The output capacitor (C<sub>OUT</sub>) maintains the DC output voltage. Use ceramic, tantalum, or low-

ESR electrolytic capacitors. For the best results, use low-ESR capacitors to keep  $\Delta V_{OUT}$  low.

For ceramic capacitors, the capacitance dominates the impedance at the switching frequency and causes the majority of the output voltage ripple. For simplification, the output voltage ripple ( $\Delta V_{OUT}$ ) can be calculated with Equation (10):

$$\Delta V_{\text{OUT}} = \frac{V_{\text{OUT}}}{8 \times f_{\text{SW}}^2 \times L \times C_{\text{OUT}}} \times (1 - \frac{V_{\text{OUT}}}{V_{\text{IN}}})$$
 (10)

For tantalum or electrolytic capacitors, the ESR dominates the impedance at the switching frequency. For simplification, the output voltage ripple ( $\Delta V_{OUT}$ ) can be estimated with Equation (11):

$$\Delta V_{\text{OUT}} = \frac{V_{\text{OUT}}}{f_{\text{SW}} \times L} \times (1 - \frac{V_{\text{OUT}}}{V_{\text{IN}}}) \times R_{\text{ESR}}$$
 (11)

When selecting  $C_{\text{OUT}}$ , consider the allowable overshoot in  $V_{\text{OUT}}$  if the load is suddenly removed. In this scenario, energy stored in the inductor is transferred to  $C_{\text{OUT}}$ , causing its voltage to rise. To achieve an optimal overshoot relative to the regulated voltage,  $C_{\text{OUT}}$  can be estimated with Equation (12):

$$C_{OUT} = \frac{I_{OUT}^2 \times L}{V_{OUT}^2 \times ((V_{OUTMAX} / V_{OUT})^2 - 1)}$$
(12)

Where  $V_{\text{OUTMAX}} / V_{\text{OUT}}$  is the allowable maximum overshoot.

After calculating the capacitance that meets both the ripple and overshoot requirements, choose the larger capacitance. When  $V_{\text{OUT}}$  is below 3.3V, it is recommended for  $C_{\text{OUT}}$  to be above 100µF.

The characteristics of the output capacitor also affect the stability of the regulation system. The MP4322 can be optimized for a wide range of capacitances and ESR values.

### **VIN Over-Voltage Protection (OVP)**

If  $V_{\text{IN}}$  exceeds above its over-voltage (OV) rising threshold (typically 37.5V), the MP4322 stops switching. Once  $V_{\text{IN}}$  drops back to the OV falling threshold (typically 36.5V), the device resumes normal operation.

### **Peak and Valley Current Limits**

Both the HS-FET and LS-FET have cycle-bycycle current limit protection. If the inductor current (I<sub>L</sub>) reaches the high-side (HS) peak current limit (typically 3.4A) during the HS-FET on time, the HS-FET is immediately forced off to prevent the current from rising further.

When the LS-FET is on, the next clock's rising edge is held until  $I_L$  drops below the low-side (LS) valley current limit (typically 2.7A). Once the HS-FET turns on again,  $I_L$  drops to a sufficiently low value. This current limit scheme prevents current runaway if an overload or short-circuit event occurs.

### **Short-Circuit Protection (SCP)**

If the output is shorted to ground and  $V_{\text{OUT}}$  drops below 70% of its nominal voltage, then the part shuts down and discharges  $V_{\text{SS}}$ . Once  $V_{\text{SS}}$  is fully discharged, the device initiates SS and attempts normal operation. This hiccup process is repeated until the fault is removed.

# Output Over-Voltage Protection (OVP) and Discharge

If  $V_{\text{OUT}}$  exceeds 130% of its nominal voltage, the MP4322 stops switching. An internal 75 $\Omega$  discharge path from FB to AGND discharges  $V_{\text{OUT}}$ . This discharge path is only active if the output is fixed. Once  $V_{\text{OUT}}$  drops below 125% of its nominal voltage, the discharge path is disabled and the part resumes normal operation.

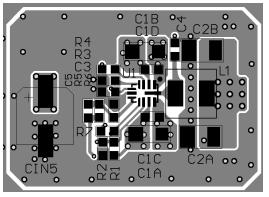

For the fixed-output version, the  $V_{\text{OUT}}$  discharge path also activates if a shutdown through EN occurs while  $V_{\text{CC}}$  exceeds its under-voltage lockout (UVLO) rising threshold. Once  $V_{\text{CC}}$  drops below its UVLO threshold, the discharge path is deactivated.

4/6/2023

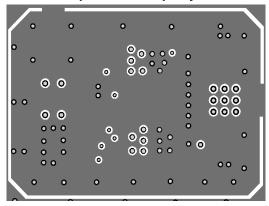

Efficient PCB layout is critical for stable operation. A 4-layer layout is strongly recommended achieve better thermal performance. For the best results, refer to Figure 11 and follow the guidelines below:

- Place the symmetric input capacitors as close to VIN and GND as possible.
- 2. Connect a large ground plane directly to PGND.
- 3. If the bottom layer is a ground plane, add vias near PGND.
- 4. Ensure that the high-current paths at PGND and VIN have short, direct, and wide traces.
- Place the ceramic input capacitor, especially the small package size (0603) input bypass capacitor, as close to VIN and PGND as possible to minimize high-frequency noise.
- 6. Keep the connection between the input capacitor and VIN as short and wide as possible.
- 7. Place the VCC capacitor as close to VCC and AGND as possible.
- Route SW and BOOT away from sensitive analog areas, such as FB.
- 9. Place the feedback resistors close to the chip, and ensure that the trace that connects to FB is as short as possible.
- 10. Use multiple vias to connect the power planes to the internal layers.

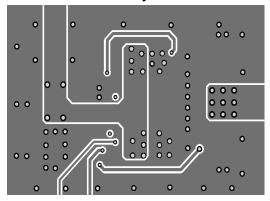

15) The recommended PCB layout is based on Figure 7 on page 30.
