

PART NUMBER NSC800DB-ROCV

Rochester Electronics Manufactured Components

Rochester branded components are manufactured using either die/wafers purchased from the original suppliers or Rochester wafers recreated from the original IP. All re-creations are done with the approval of the Original Component Manufacturer. (OCM)

Parts are tested using original factory test programs or Rochester developed test solutions to guarantee product meets or exceeds the OCM data sheet.

Quality Overview

- ISO-9001
- AS9120 certification
- Qualified Manufacturers List (QML) MIL-PRF-38535
 - Class Q Military
 - Class V Space Level

Qualified Suppliers List of Distributors (QSLD)

 Rochester is a critical supplier to DLA and meets all industry and DLA standards.

Rochester Electronics, LLC is committed to supplying products that satisfy customer expectations for quality and are equal to those originally supplied by industry manufacturers.

The original manufacturer's datasheet accompanying this document reflects the performance and specifications of the Rochester manufactured version of this device. Rochester Electronics guarantees the performance of its semiconductor products to the original OCM specifications. 'Typical' values are for reference purposes only. Certain minimum or maximum ratings may be based on product characterization, design, simulation, or sample testing.

National Semiconductor is now part of Texas Instruments.

Search http://www.ti.com/ for the latest technical information and details on our current products and services.

NSC800

NSC800™ High-Performance Low-Power CMOS Microprocessor

General Description

The NSC800 is an 8-bit CMOS microprocessor that functions as the central processing unit (CPU) in National Semiconductor's NSC800 microcomputer family. National's microCMOS technology used to fabricate this device provides system designers with performance equivalent to comparable NMOS products, but with the low power advantage of CMOS. Some of the many system functions incorporated on the device, are vectored priority interrupts, refresh control, power-save feature and interrupt acknowledge. The NSC800 is available in dual-in-line and surface mounted chip carrier packages.

The system designer can choose not only from the dedicated CMOS peripherals that allow direct interfacing to the NSC800 but from the full line of National's CMOS products to allow a low-power system solution. The dedicated peripherals include NSC810A RAM I/O Timer, NSC858 UART, and NSC831 I/O.

All devices are available in commercial, industrial and military temperature ranges along with two added reliability flows. The first is an extended burn in test and the second is the military class C screening in accordance with Method 5004 of MIL-STD-883.

Features

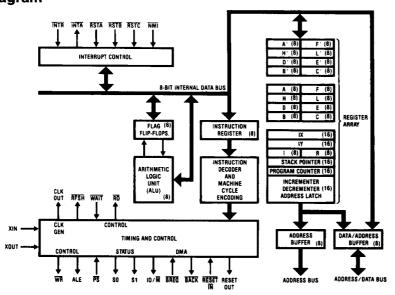

- Fully compatible with Z80® instruction set: Powerful set of 158 instructions 10 addressing modes 22 internal registers
- Low power: 50 mW at 5V V_{CC}
- Unique power-save feature
- Multiplexed bus structure
- Schmitt trigger input on reset
- On-chip bus controller and clock generator
- Variable power supply 2.4V-6.0V
- On-chip 8-bit dynamic RAM refresh circuitry
- Speed: 1.0 µs instruction cycle at 4.0 MHz NSC800-4 4.0 MHz

NSC800-35 3.5 MHz NSC800-3 2.5 MHz

NSC800-1 1.0 MHz

- Capable of addressing 64k bytes of memory and 256 I/O devices
- Five interrupt request lines on-chip

Note 1: Absolute Maximum Ratings indicate limits beyond which permanent damage may occur. Continuous operation at these limits is not intended and should be limited to those conditions specified under DC Electrical Characteristics.

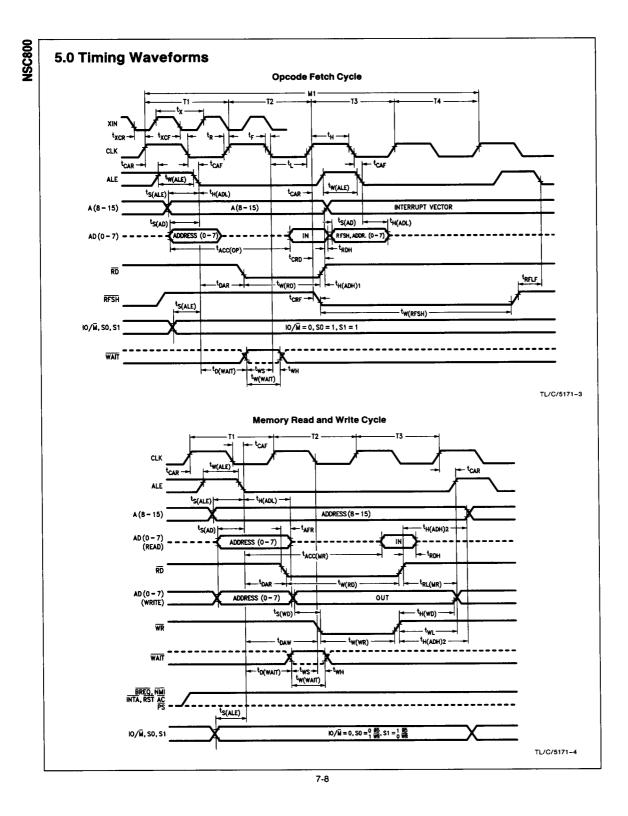

Note 2: CPU operation at lower voltages will reduce the maximum operating speed. Operation at voltages other than 5V ±10% is guaranteed by design, not tested.

Note 2: Output timings are measured with a purely capacitive load of 100 pF.

7-9

NSC800 HARDWARE

6.0 Pin Descriptions

6.1 INPUT SIGNALS

Reset Input (RESET IN): Active low. Sets A (8-15) and AD (0-7) to TRI-STATE® (high impedance). Clears the contents of PC, I and R registers, disables interrupts, and activates reset out.

Bus Request (BREQ): Active low. Used when another device requests the system bus. The NSC800 recognizes $\overline{\text{BREQ}}$ at the end of the current machine cycle, and sets A(8–15), AD(0–7), IO/ $\overline{\text{M}}$, $\overline{\text{RD}}$, and $\overline{\text{WR}}$ to the high impedance state. $\overline{\text{RFSH}}$ is high during a bus request cycle. The CPU acknowledges the bus request via the $\overline{\text{BACK}}$ output signal.

Non-Maskable Interrupt (NMI): Active low. The non-maskable interrupt, generated by the peripheral device(s), is the highest priority interrupt. The edge sensitive interrupt requires only a pulse to set an internal filip-flop which generates the internal interrupt request. The NMI flip-flop is monitored on the same clock edge as the other interrupts. It must also meet the minimum set-up time spec for the interrupt to be accepted in the current machine instruction. When the processor accepts the interrupt the flip-flop resets automatically. Interrupt execution is independent of the interrupt enable flip-flop. NMI execution results in saving the PC on the stack and automatic branching to restart address X'0066 in memory.

Restart Interrupts, A, B, C (RSTA, RSTB, RSTC): Active low level sensitive. The CPU recognizes restarts generated by the peripherals at the end of the current instruction, if their respective interrupt enable and master enable bits are set. Execution is identical to NMI except the interrupts vector to the following restart addresses:

Name	Restart		
Name	Address (X')		
NMI	0066		
RSTA	003C		
RSTB	0034		
RSTC	002C		
INTR (Mode 1)	0038		

The order of priority is fixed. The list above starts with the highest priority.

Interrupt Request (INTR): Active low, level sensitive. The CPU recognizes an interrupt request at the end of the current instruction provided that the interrupt enable and master interrupt enable bits are set. INTR is the lowest priority interrupt. Program control selects one of three response modes which determines the method of servicing INTR in conjunction with INTA. See Interrupt Control.

Walt (WAIT): Active low. When set low during RD, WR or INTA machine cycles (during the WR machine cycle, wait must be valid prior to write going active) the CPU extends its machine cycle in increments of t (wait) states. The wait machine cycle continues until the WAIT input returns high.

The wait strobe input will be accepted only during machine cycles that have RD, WR or INTA strobes and during the machine cycle immediately after an interrupt has been accepted by the CPU. The later cycle has its RD strobe suppressed but it will still accept the wait.

Power-Save (PS): Active low. PS is sampled during the last t state of the current instruction cycle. When PS is low, the

CPU stops executing at the end of current instruction and keeps itself in the low-power mode. Normal operation resumes when $\overline{\text{PS}}$ returns high (see Power Save Feature description).

CRYSTAL (X_{IN}, X_{OUT}): X_{IN} can be used as an external clock input. A crystal can be connected across X_{IN} and X_{OUT} to provide a source for the system clock.

6.2 OUTPUT SIGNALS

Bus Acknowledge (BACK): Active low. BACK indicates to the bus requesting device that the CPU bus and its control signals are in the TRI-STATE mode. The requesting device then commands the bus and its control signals.

Address Bits 8-15 [A(8-15)]: Active high. These are the most significant 8 bits of the memory address during a memory instruction. During an I/O instruction, the port address on the lower 8 address bits gets duplicated onto A(8-15). During a BREQ/BACK cycle, the A(8-15) bus is in the TRI-STATE mode.

Reset Out (RESET OUT): Active high. When RESET OUT is high, it indicates the CPU is being reset. This signal is normally used to reset the peripheral devices.

Input/Output/Memory (IO/ $\overline{\mathbf{M}}$): An active high on the IO/ $\overline{\mathbf{M}}$ output signifies that the current machine cycle is an input/output cycle. An active low on the IO/ $\overline{\mathbf{M}}$ output signifies that the current machine cycle is a memory cycle. It is TRI-STATE during $\overline{\mathbf{BREO}}/\overline{\mathbf{BACK}}$ cycles.

Refresh (RFSH): Active low. The refresh output indicates that the dynamic RAM refresh cycle is in progress. RFSH goes low during T3 and T4 states of all M1 cycles. During the refresh cycle, AD(0-7) has the refresh address and A(8-15) indicates the interrupt vector register data. RFSH is high during BREQ/BACK cycles.

Address Latch Enable (ALE): Active high. ALE is active only during the T1 state of any M cycle and also T3 state of the M1 cycle. The high to low transition of ALE indicates that a valid memory, I/O or refresh address is available on the AD(0-7) lines.

Read Strobe (RD): Active low. The CPU receives data via the AD(0-7) lines on the trailing edge of the RD strobe. The RD line is in the TRI-STATE mode during BREQ/BACK cycles.

Write Strobe (WR): Active low. The CPU sends data via the AD(0-7) lines while the \overline{WR} strobe is low. The \overline{WR} line is in the TRI-STATE mode during $\overline{BREQ}/\overline{BACK}$ cycles.

Clock (CLK): CLK is the output provided for use as a system clock. The CLK output is a square wave at one half the input frequency.

Interrupt Acknowledge (INTA): Active low. This signal strobes the interrupt response vector from the interrupting peripheral devices onto the AD(0-7) lines. INTA is active during the M1 cycle immediately following the t state where the CPU recognized the INTR interrupt request.

Two of the three interrupt request modes use $\overline{\text{INTA}}$. In mode 0 one to four $\overline{\text{INTA}}$ signals strobe a one to four byte instruction onto the AD(0-7) lines. In mode 2 one $\overline{\text{INTA}}$ signal strobes the lower byte of an interrupt response vector onto the bus. In mode 1, $\overline{\text{INTA}}$ is inactive and the CPU response to $\overline{\text{INTR}}$ is the same as for an NMI or restart interrupt.

6.0 Pin Descriptions (Continued)

Status (SO, S1): Bus status outputs provide encoded information regarding the current M cycle as follows:

Machine Cycle		State	Control		
	SO	S1	IO/M	RD	WR
Opcode Fetch	1	1	0	0	1
Memory Read	0	1	0	0	1
Memory Write	1	0	0	1	0
I/O Read	0	1	1	0	1
I/O Write	1	0	1	1	0
Halt*	0	0	0	0	1
Internal Operation*	0	1	0	1	1
Acknowledge of Int**	1	1	0	1	1

^{*}ALE is not suppressed in this cycle.

Note 1: During halt, CPU continues to do dummy opcode fetch from location following the halt instruction with a halt status. This is so CPU can continue to do its dynamic RAM refresh.

Note 2: No early status is provided for interrupt or hardware restarts.

6.3 INPUT/OUTPUT SIGNALS

Multiplexed Address/Data [AD(0-7)]: Active high At RD Time: Input data to CPU.

At RD Time: Input data to CPU.
At WR Time: Output data from CPU.
At Falling Edge Least significant byte of

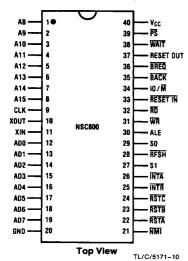

At Falling Edge Least significant byte of address of ALE Time: during memory reference cycle. 8-bit

port address during I/O reference

During BREQ/ High impedance.
BACK Cycle:

^{**}This is the cycle that occurs immediately after the CPU accepts an interrupt (RSTA, RSTB, RSTC, INTR, NMI).

8.0 Functional Description

This section reviews the CPU architecture shown below, focusing on the functional aspects from a hardware perspective, including timing details.

As illustrated in *Figure 1*, the NSC800 is an 8-bit parallel device. The major functional blocks are: the ALU, register array, interrupt control, timing and control logic. These areas are connected via the 8-bit internal data bus. Detailed descriptions of these blocks ae provided in the following sections.

Note: Applicable pinout for 40-pin dual-in-line package within parentheses

FIGURE 1. NSC800 CPU Functional Block Diagram

7-12

8.0 Functional Description (Continued)

8.1 REGISTER ARRAY

The NSC800 register array is divided into two parts: the dedicated registers and the working registers, as shown in *Figure 2*.

Main Reg.	Set	Alternate Reg. Set				
Accumulator	Flags	Accumulator	Flags

Index Regi	Index Register IY			
Stack Pointer SP				
Program C] ,			

FIGURE 2. NSC800 Register Array

8.2 DEDICATED REGISTERS

There are 6 dedicated registers in the NSC800: two 8-bit and four 16-bit registers (see *Figure 3*).

Although their contents are under program control, the program has no control over their operational functions, unlike the CPU working registers. The function of each dedicated register is described as follows:

CPU Dedicated Registers

Program Counter PC	(16)
Stack Pointer SP	(16)
Index Register IX	(16)
Index Register IY	(16)
Interrupt Vector Register I	(8)
Memory Refresh Register R	(8)

FIGURE 3. Dedicated Registers

8.2.1 Program Counter (PC)

The program counter contains the 16-bit address of the current instruction being fetched from memory. The PC increments after its contents have been transferred to the address lines. When a program jump occurs, the PC receives the new address which overrides the incrementer.

There are many conditional and unconditional jumps, calls, and return instructions in the NSC800's instruction repertoire that allow easy manipulation of this register in controlling the program execution (i.e. JP NZ nn, JR Zd2, CALL NC nn)

8.2.2 Stack Pointer (SP)

The 16-bit stack pointer contains the address of the current top of stack that is located in external system RAM. The stack is organized in a last-in, first-out (LIFO) structure. The pointer decrements before data is pushed onto the stack, and increments after data is popped from the stack.

Various operations store or retrieve, data on the stack. This, along with the usage of subroutine calls and interrupts, allows simple implementation of subroutine and interrupt nesting as well as alleviating many problems of data manipulation.

8.2.3 Index Register (IX and IY)

The NSC800 contains two index registers to hold independent, 16-bit base addresses used in the indexed addressing mode. In this mode, an index register, either IX or IY, contains a base address of an area in memory making it a pointer for data tables.

In all instructions employing indexed modes of operation, another byte acts as a signed two's complement displacement. This addressing mode enables easy data table manipulations.

8.2.4 Interrupt Register (i)

When the NSC800 provides a Mode 2 response to $\overline{\text{INTR}}$, the action taken is an indirect call to the memory location containing the service routine address. The pointer to the address of the service routine is formed by two bytes, the high-byte is from the I Register and the low-byte is from the interrupting peripheral. The peripheral always provides an even address for the lower byte (LSB=0). When the processor receives the lower byte from the peripheral it concatenates it in the following manner:

l Register	External byte	
8 bits		0
		<u></u> ↑

The LSB of the external byte must be zero.

FIGURE 4a. Interrupt Register

The even memory location contains the low-order byte, the next consecutive location contains the high-order byte of the pointer to the beginning address of the interrupt service routine.

8.2.5 Refresh Register (R)

For systems that use dynamic memories rather than static RAM's, the NSC800 provides an integral 8-bit memory refresh counter. The contents of the register are incremented after each opcode fetch and are sent out on the lower portion of the address bus, along with a refresh control signal. This provides a totally transparent refresh cycle and does not slow down CPU operation.

The program can read and write to the R register, although this is usually done only for test purposes.

8.0 Functional Description (Continued)

8.3 CPU WORKING AND ALTERNATE REGISTER SETS 8.3.1 CPU Working Registers

The portion of the register array shown in *Figure 4b* represents the CPU working registers. These sixteen 8-bit registers are general-purpose registers because they perform a multitude of functions, depending on the instruction being executed. They are grouped together also due to the types of instructions that use them, particularly alternate set operations.

The F (flag) register is a special-purpose register because its contents are more a result of machine status rather than program data. The F register is included because of its interaction with the A register, and its manipulations in the alternate register set operations.

8.3.2 Alternate Registers

The NSC800 registers designated as CPU working registers have one common feature: the existence of a duplicate register in an alternate register set. This architectural concept simplifies programming during operations such as interrupt response, when the machine status represented by the contents of the registers must be saved.

The alternate register concept makes one set of registers available to the programmer at any given time. Two instructions (EX AF, A'F' and EXX), exchange the current working set of registers with their alternate set. One exchange between the A and F registers and their respective duplicates (A' and F') saves the primary status information contained in the accumulator and the flag register. The second exchange instruction performs the exchange between the remaining registers, B, C, D, E, H, and L, and their respective alternates B', C', D', E', H', and L'. This essentially saves the contents of the original complement of registers while providing the programmer with a usable alternate set.

CPU Main Working Register Set

Accumulator A	(8)	Flags F	(8)
Register B	(8)	Register C	(8)
Register D	(8)	Register E	(8)
Register H	(8)	Register L	(8)

CPU Alternate Working Register Set

Accumulator A'	(8)	Flags F'	(8)
Register B'	(8)	Register C'	(8)
Register D'	(8)	Register E'	(8)
Register H'	(8)	Register L'	(8)

FIGURE 4b. CPU Working and Alternate Registers

8.4 REGISTER FUNCTIONS

8.4.1 Accumulator (A Register)

The A register serves as a source or destination register for data manipulation instructions. In addition, it serves as the accumulator for the results of 8-bit arithmetic and logic operations.

The A register also has a special status in some types of operations; that is, certain addressing modes are reserved for the A register only, although the function is available for all the other registers. For example, any register can be loaded by immediate, register indirect, or indexed addressing modes. The A register, however, can also be loaded via an additional register indirect addressing.

Another special feature of the A register is that it produces more efficient memory coding than equivalent instruction functions directed to other registers. Any register can be rotated; however, while it requires a two-byte instruction to normally rotate any register, a single-byte instruction is available for rotating the contents of the accumulator (A register).

8.4.2 F Register - Flags

The NSC800 flag register consists of six status bits that contain information regarding the results of previous CPU operations. The register can be read by pushing the contents onto the stack and then reading it, however, it cannot be written to. It is classified as a register because of its affiliation with the accumulator and the existence of a duplicate register for use in exchange instructions with the accumulator.

Of the six flags shown in Figure 5, only four can be directly tested by the programmer via conditional jump, call, and return instructions. They are the Sign (S), Zero (Z), Parity/Overflow (P/V), and Carry (C) flags. The Half Carry (H) and Add/Subtract (N) flags are used for internal operations related to BCD arithmetic.

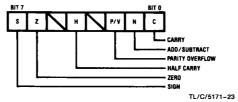

FIGURE 5. Flag Register

8.0 Functional Description (Continued) 8.4.3 Carry (C)

A carry from the highest order bit of the accumulator during an add instruction, or a borrow generated during a subtraction instruction sets the carry flag. Specific shift and rotate instructions also affect this bit.

Two specific instructions in the NSC800 instruction repertoire set (SCF) or complement (CCF) the carry flag.

Other operations that affect the C flag are as follows:

- Adds
- Subtracts
- Logic Operations (always resets C flag)
- Rotate Accumulator
- Rotate and Shifts
- Decimal Adjust
- Negation of Accumulator

Other operations do not affect the C flag.

8.4.4 Adds/Subtract (N)

This flag is used in conjunction with the H flag to ensure that the proper BCD correction algorithm is used during the decimal adjust instruction (DAA). The correction algorithm depends on whether an add or subtract was previously done with BCD operands.

The operations that set the N flag are:

- Subtractions
- Decrements (8-bit)
- · Complementing of the Accumulator
- Block I/O
- Block Searches
- Negation of the Accumulator

The operations that reset the N flag are:

- Adds
- Increments
- Logic Operations
- Rotates
- Set and Complement Carry
- Input Register Indirect
- Block Transfers
- Load of the I or R Registers
- Bit Tests

Other operations do not affect the N flag.

8.4.5 Parity/Overflow (P/V)

The Parity/Overflow flag is a dual-purpose flag that indicates results of logic and arithmetic operations. In logic operations, the P/V flag indicates the parity of the result; the flag is set (high) if the result is even, reset (low) if the result is odd. In arithmetic operations, it represents an overflow condition when the result, interpreted as signed two's complement arithmetic, is out of range for the eight-bit accumulator (i.e. $-128\ {\rm to}\ +127)$).

The following operations affect the P/V flag according to the parity of the result of the operation:

- Logic Operations
- Rotate and Shift
- Rotate Digits
- Decimal Adjust
- Input Register Indirect

The following operations affect the P/V flag according to the overflow result of the operation.

- Adds (16 bit with carry, 8-bit with/without carry)
- Subtracts (16 bit with carry, 8-bit with/without carry)
- Increments and Decrements
- Negation of Accumulator

The P/V flag has no significance immediately after the following operations.

- Block I/O
- Bit Tests

In block transfers and compares, the P/V flag indicates the status of the BC register, always ending in the reset state after an auto repeat of a block move. Other operations do not affect the P/V flag.

8.4.6 Half Carry (H)

This flag indicates a BCD carry, or borrow, result from the low-order four bits of operation. It can be used to correct the results of a previously packed decimal add, or subtract, operation by use of the Decimal Adjust Instruction (DAA).

The following operations affect the H flag:

- Adds (8-bit)
- Subtracts (8-bit)
- · Increments and Decrements
- Decimal Adjust
- Negation of Accumulator
- Always Set by: Logic AND

Complement Accumulator

Bit Testing

Always Reset By: Logic OR's and XOR's

Rotates and Shifts

Set Carry

Input Register Indirect

Block Transfers

Loads of I and R Registers

The H flag has no significance immediately after the following operations.

- 16-bit Adds with/without carry
- 16-Bit Subtracts with carry
- Complement of the carry
- Block I/O
- Block Searches

Other operations do not affect the H flag.

8.0 Functional Description (Continued)

8.4.7 Zero Flag (Z)

Loading a zero in the accumulator or when a zero results from an operation sets the zero flag.

The following operations affect the zero flag.

- Adds (16-bit with carry, 8-bit with/without carry)
- Subtracts (16-bit with carry, 8-bit with/without carry)
- Logic Operations
- Increments and Decrements
- Rotate and Shifts
- Rotate Digits
- Decimal Adjust
- Input Register Indirect
- Block I/O (always set after auto repeat block I/O)
- Block Searches
- Load of I and R Registers
- Bit Tests
- Negation of Accumulator

The Z flag has no signficance immediately after the following operations:

Block Transfers

Other operations do not affect the zero flag.

8.4.8 Sign Flag (S)

The sign flag stores the state of bit 7 (the most-significant bit and sign bit) of the accumulator following an arithmetic operation. This flag is of use when dealing with signed numbers.

The sign flag is affected by the following operation according to the result:

- Adds (16-bit with carry, 8-bit with/without carry)
- Subtracts (16-bit with carry, 8-bit with/without carry)
- Logic Operations
- Increments and Decrements
- Rotate and Shifts
- Rotate Digits
- Decimal Adjust
- Input Register Indirect
- Block Search
- Load of I and R Registers
- Negation of Accumulator

The S flag has no significance immediately after the following operations:

- Block I/O
- Block Transfers
- Bit Tests

Other operations do not affect the sign bit.

8.4.9 Additional General-Purpose Registers

The other general-purpose registers are the B, C, D, E, H and L registers and their alternate register set, B', C', D', E', H' and L'. The general-purpose registers can be used interchangeably.

In addition, the B and C registers perform special functions in the NSC800 expanded I/O capabilities, particularly block I/O operations. In these functions, the C register can address I/O ports; the B register provides a counter function when used in the register indirect address mode.

When used with the special condition jump instruction (DJNZ) the B register again provides the counter function.

8.4.10 Alternate Configurations

The six 8-bit general purpose registers (B,C,D,E,H,L) will combine to form three 16-bit registers. This occurs by concatenating the B and C registers to form the BC register, the D and E registers form the DE register, and the H and L registers form the HL register.

Having these 16-bit registers allows 16-bit data handling, thereby expanding the number of 16-bit registers available for memory addressing modes. The HL register typically provides the pointer address for use in register indirect addressing of the memory.

The DE register provides a second memory pointer register for the NSC800's powerful block transfer operations. The BC register also provides an assist to the block transfer operations by acting as a byte-counter for these operations.

8.5 ARITHMETIC-LOGIC UNIT (ALU)

The arithmetic, logic and rotate instructions are performed by the ALU. The ALU internally communicates with the registers and data buffer on the 8-bit internal data bus.

8.6 INSTRUCTION REGISTER AND DECODER

During an opcode fetch, the first byte of an instruction is transferred from the data buffer (i.e. its on the internal data bus) to the instruction register. The instruction register feeds the instruction decoder, which gated by timing signals, generates the control signals that read or write data from or to the registers, control the ALU and provide all required external control signals.

9.0 Timing and Control

9.1 INTERNAL CLOCK GENERATOR

An inverter oscillator contained on the NSC800 chip provides all necessary timing signals. The chip operation frequency is equal to one half of the frequency of this oscillator.

The oscillator frequency can be controlled by one of the following methods:

1. Leaving the X_{OUT} pin unterminated and driving the X_{IN} pin with an externally generated clock as shown in *Figure 6*. When driving X_{IN} with a square wave, the minimum duty cycle is 30% high.

TL/C/5171-13

FIGURE 6. Use of External Clock

 Connecting a crystal with the proper biasing network between X_{IN} and X_{OUT} as shown in Figure 7. Recommended crystal is a parallel resonance AT cut crystal.

Note 1: If the crystal frequency is between 1 MHz and 2 MHz a series resistor, R_S, (470Ω to 1500Ω) should be connected between X_{OUT} and R, XTAL and C_Z. Additionally, the capacitance of C1 and C2 should be increased by 2 to 3 times the recommended value. For crystal frequencies less than 1 MHz higher values of C1 and C2 may be required. Crystal parameters will also affect the capacitive loading requirements.

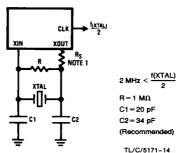

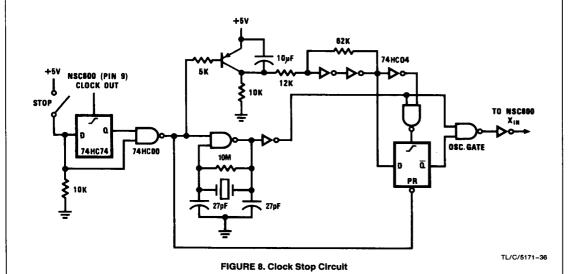

FIGURE 7. Use Of Crystal

The CPU has a minimum clock frequency input (@ X_{IN}) of 300 kHz, which results in 150 kHz system clock speed. All registers internal to the chip are static, however there is dynamic logic which limits the minimum clock speed. The input clock can be stopped without fear of losing any data or damaging the part. You stop it in the phase of the clock that has X_{IN} low and CLK OUT high. When restarting the CPU, precautions must be taken so that the input clock meets these minimum specification. Once started, the CPU will continue operation from the same location at which it was stopped. During DC operation of the CPU, typical current drain will be 2 mA. This current drain can be reduced by placing the CPU in a wait state during an opcode fetch cycle then stopping the clock. For clock stop circuit, see *Figure 8*.

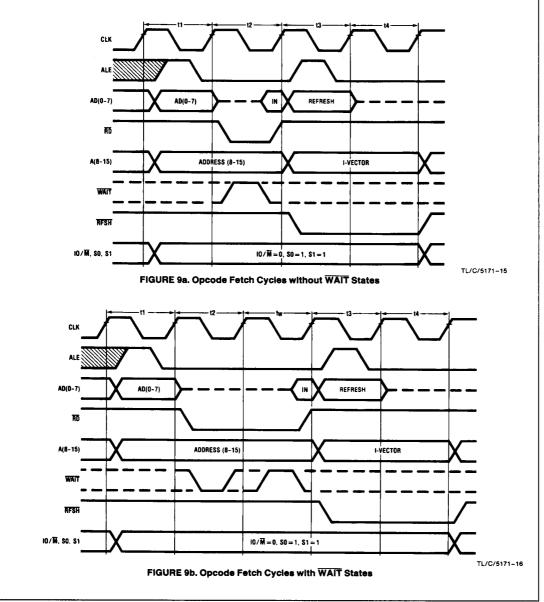

9.2 CPU TIMING

The NSC800 uses a multiplexed bus for data and addresses. The 16-bit address bus is divided into a high-order 8-bit address bus that handles bits 8–15 of the address, and a low-order 8-bit multiplexed address/data bus that handles bits 0–7 of the address and bits 0–7 of the data. Strobe outputs from the NSC800 (ALE, $\overline{\text{RD}}$ and $\overline{\text{WR}}$) indicate when a valid address or data is present on the bus. IO/ $\overline{\text{M}}$ indicates whether the ensuing cycle accesses memory or I/O.

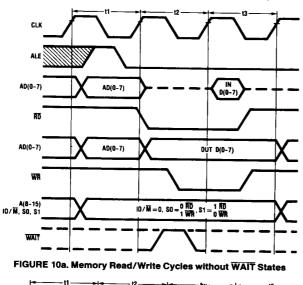

During an input or output instruction, the CPU duplicates the lower half of the address [AD(0-7)] onto the upper address bus [A(8-15)]. The eight bits of address will stay on A(8-15) for the entire machine cycle and can be used for chip selection directly.

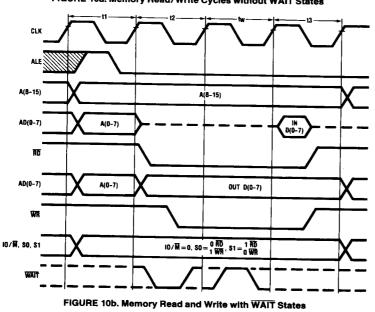

Figure 9 illustrates the timing relationship for opcode fetch cycles with and without a wait state.

During the opcode fetch, the CPU places the contents of the PC on the address bus. The falling edge of ALE indicates a valid address on the AD(0-7) lines. The WAIT input is sampled during t_2 and if active causes the NSC800 to insert a wait state (t_w). WAIT is sampled again during t_w so

that when it goes inactive, the CPU continues its opcode fetch by latching in the data on the rising edge of \overline{RD} from the AD(0–7) lines. During t_3 , \overline{RFSH} goes active and AD(0–7) has the dynamic RAM refresh address from register R and A(8–15) the interrupt vector from register I.

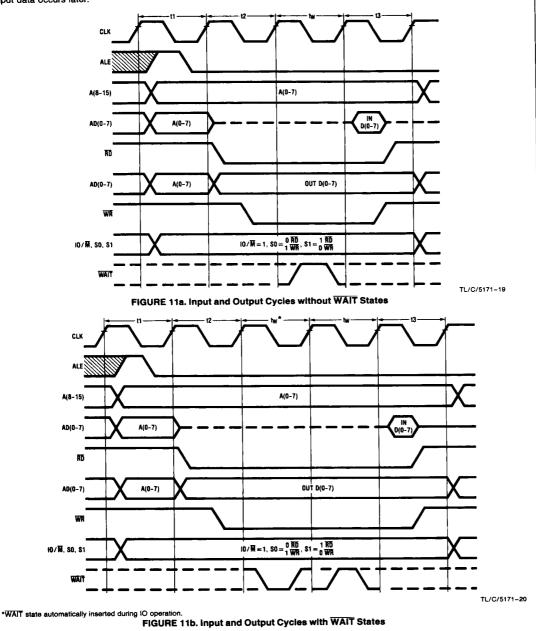

TL/C/5171-17

5

TL/C/5171-18

Figure 10 shows the timing for memory read (other than opcode fetchs) and write cycles with and without a wait state. The $\overline{\text{RD}}$ stobe is widened by $\frac{\text{t}}{2}$ (half the machine state) for memory reads so that the actual latching of the input data occurs later.

Figure 11 shows the timing for input and output cycles with and without wait states. The CPU automatically inserts one wait state into each I/O instruction to allow sufficient time for an I/O port to decode the address.

9.3 INITIALIZATION

RESET IN initializes the NSC800; RESET OUT initializes the peripheral components. The Schmitt trigger at the RESET IN input facilitates using an R-C network reset scheme during power up (see Figure 12).

To ensure proper power-up conditions for the NSC800, the following power-up and initialization procedure is recommended:

- 1. Apply power (V_{CC} and GND) and set RESET IN active (low). Allow sufficient time (approximately 30 ms if a crystal is used) for the oscillator and internal clocks to stabilize. RESET IN must remain low for at least 3t state (CLK) times. RESET OUT goes high as soon as the active RESET IN signal is clocked into the first flip-flop after the on-chip Schmitt trigger. RESET OUT signal is available to reset the peripherals.
- Set RESET IN high. RESET OUT then goes low as the inactive RESET IN signal is clocked into the first flip-flop after the on-chip Schmitt trigger. Following this the CPU initiates the first opcode fetch cycle.

Note: The NSC800 initialization includes: Clear PC to X'0000 (the first opcode fetch, therefore, is from memory location X'0000). Clear registers I (Interrupt Vector Base) and R (Refresh Counter) to X'00. Clear interrupt control register bits IEA, IEB and IEC. The interrupt control bit IEI is set to 1 to maintain INS8080A/Z80A compatibility (see INTER-RUPTS for more details). The CPU disables maskable interrupts and enters INTR Mode 0. While RESET IN is active (low), the A(8–15) and AD(0–7) lines go to high impedance (TRI-STATE) and all CPU strobes go to the inactive state (see Figure 13).

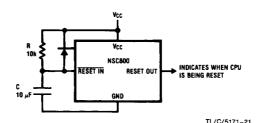

FIGURE 12. Power-On Reset

9.4 POWER-SAVE FEATURE

The NSC800 provides a unique power-save mode by the means of the PS pin. PS input is sampled at the last t state of the last M cycle of an instruction. After recognizing an active (low) level on PS, The NSC800 stops its internal clocks, thereby reducing its power dissipation to one half of operating power, yet maintaining all register values and internal control status. The NSC800 keeps its oscillator running, and makes the CLK signal available to the system. When in power-save the ALE strobe will be stopped high and the address lines [AD(0-7), A(8-15)] will indicate the next machine address. When PS returns high, the opcode fetch (or M1 cycle) of the CPU begins in a normal manner. Note this M1 cycle could also be an interrupt acknowledge cycle if the NSC800 was interrupted simultaneously with PS (i.e. PS has priority over a simultaneously occurring interrupt). However, interrupts are not accepted during power save. Figure 14 illustrates the power save timing.

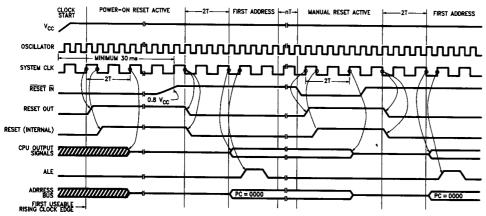

FIGURE 13. NSC800 Signals During Power-On and Manual Reset

TL/C/5171-74

9.0 Timing and Control (Continued) LAST M CYCLE OF MISTRUCTION ADDG-77 ALE FIGURE 14. NSC800 Power-Save ANY M CYCLE BAER ANY M CYCLE BAER ANY M CYCLE BASS AWAILABLE STATES SO. S1 SO. S1

*S0, S1 during $\overline{B}\overline{B}\overline{E}\overline{Q}$ will indicate same machine cycle as during the cycle when $\overline{B}\overline{B}\overline{E}\overline{Q}$ was accepted. t_Z = time states during which bus and control signals are in high impedance mode.

FIGURE 15. Bus Acknowledge Cycle

In the event \overline{BREQ} is asserted (low) at the end of an instruction cycle and \overline{PS} is active simultaneously, the following occurs:

- 1. The NSC800 will go into BACK cycle.
- Upon completion of BACK cycle if PS is still active the CPU will go into power-save mode.

9.5 BUS ACCESS CONTROL

Figure 15 illustrates bus access control in the NSC800. The external device controller produces an active BREQ signal that requests the bus. When the CPU responds with BACK then the bus and related control strobes go to high impedance (TRI-STATE) and the RFSH signal remains high. It should be noted that (1) BREQ is sampled at the last t state of any M machine cycle only. (2) The NSC800 will not acknowledge any interrupt/restart requests, and will not perform any dynamic RAM refresh functions until after BREQ input signal is inactive high. (3) BREQ signal has priority over all interrupt request signals, should BREQ and interrupt request become active simultaneously. Therefore, interrupts latched at the end of the instruction cycle will be serviced after a simultaneously occurring BREQ. NMi is latched during an active BREQ.

9.6 INTERRUPT CONTROL

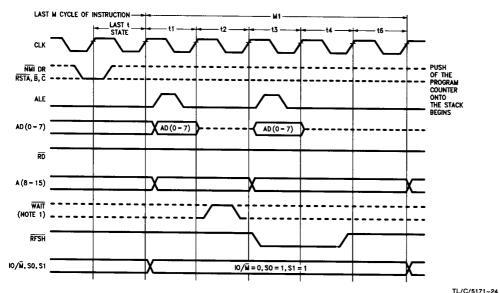

The NSC800 has five interrupt/restart inputs, four are maskable (RSTA, RSTB, RSTC, and INTR) and one is non-maskable (NMI). NMI has the highest priority of all interrupts; the user cannot disable NMI. After recognizing an active input on NMI, the CPU stops before the next instruction, pushes the PC onto the stack, and jumps to address X'0066, where the user's interrupt service routine is located (i.e., restart to memory location X'0066). NMI is intended for interrupts requiring immediate attention, such as power-down, control panel, etc.

TL/C/5171-22

RSTA, RSTB and RSTC are restart inputs, which, if enabled, execute a restart to memory location X'003C, X'0034, and X'002C, respectively. Note that the CPU response to the NMI and RST (Ā, B, C) request input is basically identical, except for the restored memory location. Unlike NMI, however, restart request inputs must be enabled.

Figure 16 illustrates NMI and RST interrupt machine cycles. M1 cycle will be a dummy opcode fetch cycle followed by M2 and M3 which are stack push operations. The following instruction then starts from the interrupts restart location.

Note: RD does *not* go low during this dummy opcode fetch. A unique indication of INTA can be decoded using 2 ALEs and RD.

Note 1: This is the only machine cycle that does not have an RD, WR, or INTA strobe but will accept a wait strobe.

FIGURE 16. Non-Maskable and Restart Interrupt Machine Cycle

The NSC800 also provides one more general purpose interrupt request input, INTR. When enabled, the CPU responds to INTR in one of the three modes defined by instruction IM0, IM1, and IM2 for modes 0, 1, and 2, respectively. Following reset, the CPU automatically enables mode 0.

Interrupt (INTR) Mode 0: The CPU responds to an interrupt request by providing an INTA (interrupt acknowledge) strobe, which can be used to gate an instruction from a peripheral onto the data bus. The CPU inserts two wait states during the first INTA cycle to allow the interrupting device (or its controller) ample time to gate the instruction and determine external priorities (Figure 18). This can be any instruction from one to four bytes. The most popular instruction is one-byte call (restart instruction) or a three-byte call (CALL NN instruction). If it is a three-byte call, the CPU issues a total of three INTA strobes. The last two (which do not include wait states) read NN.

Note: If the instruction stored in the ICU doesn't require the PC to be pushed onto the stack (eq. JP nn), then the PC will not be pushed.

Interrupt (INTR) Mode 1: Similar to restart interrupts except the restart location is X'0038 (Figure 18).

Interrupt (INTR) Mode 2: With this mode, the programmer maintains a table that contains the 16-bit starting address of every interrupt service routine. This table can be located anywhere in memory. When the CPU accepts a Mode 2 interrupt (Figure 17), it forms a 16-bit pointer to obtain the desired interrupt service routine starting address from the table. The upper 8 bits of this pointer are from the contents of the I register. The lower 8 bits of the pointer are supplied by the interrupting device with the LSB forced to zero. The programmer must load the interrupt vector prior to the interrupt occurring. The CPU uses the pointer to get the two adjacent bytes from the interrupt service routine starting address table to complete 16-bit service routine starting address table to complete 16-bit service routine starting ad-

dress. The first byte of each entry in the table is the least significant (low-order) portion of the address. The programmer must obviously fill this table with the desired addresses before any interrupts are to be accepted.

Note that the programmer can change this table at any time to allow peripherals to be serviced by different service routines. Once the interrupting device supplies the lower portion of the pointer, the CPU automatically pushes the program counter onto the stack, obtains the starting address from the table and does a jump to this address.

The interrupts have fixed priorities built into the NSC800 as:

NMI	0066	(Highest Priority)
RSTA	003C	
RSTB	0034	
RSTC	002C	
INTR	0038	(Lowest Priority)

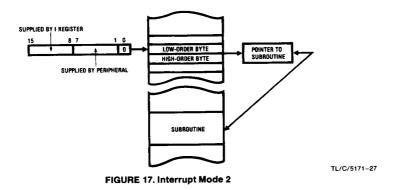

Interrupt Enable, Interrupt Disable. The NSC800 has two types of interrupt inputs, a non-maskable interrupt and four software maskable interrupts. The non-maskable interrupt (NMI) cannot be disabled by the programmer and will be accepted whenever a peripheral device requests an interrupt. The NMI is usually reserved for important functions that must be serviced when they occur, such as imminent power failure. The programmer can selectively enable or disable maskable interrupts (INT, RSTA, RSTB and RSTC). This selectivity allows the programmer to disable the maskable interrupts during periods when timing constraints don't allow program interruption.

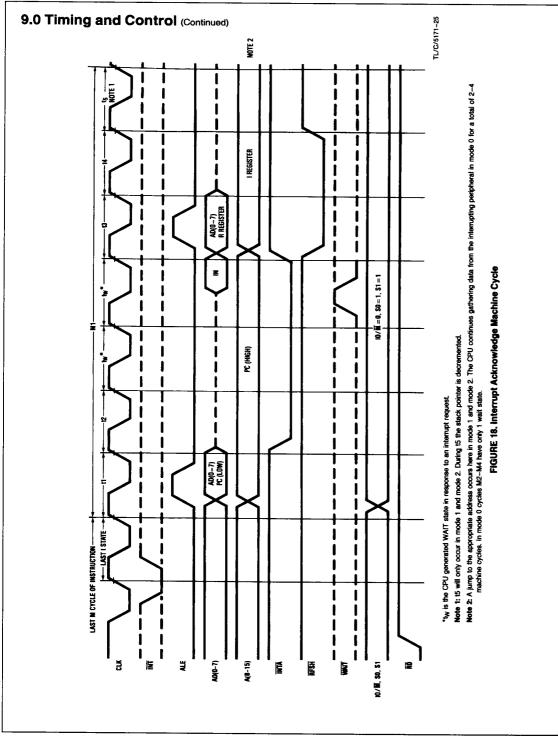

There are two interrupt enable flip-flops (IFF $_1$ and IFF $_2$) on the NSC800. Two instructions control these flip-flops. Enable Interrupt (EI) and Disable Interrupt (DI). The state of IFF $_1$ determines the enabling or disabling of the maskable interrupts, while IFF $_2$ is used as a temporary storage location for the state of IFF $_1$.

A reset to the CPU will force both IFF₁ and IFF₂ to the reset state disabling maskable interrupts. They can be enabled by an EI instruction at any time by the programmer. When an EI instruction is executed, any pending interrupt requests will not be accepted until after the instruction following EI has been executed. This single instruction delay is necessary in situations where the following instruction is a return instruction and interrupts must not be allowed until the return has been completed. The EI instruction sets both IFF₁ and IFF₂

to the enable state. When the CPU accepts an interrupt, both IFF $_1$ and IFF $_2$ are automatically reset, inhibiting further interrupts until the programmer wishes to issue a new EI instruction. Note that for all the previous cases, IFF $_1$ and IFF $_2$ are always equal.

The function of IFF $_2$ is to retain the status of IFF $_1$ when a non-maskable interrupt occurs. When a non-maskable interrupt is accepted, IFF $_1$ is reset to prevent further interrupts until reenabled by the programmer. Thus, after a non-maskable interrupt has been accepted, maskable interrupts are disabled but the previous state of IFF $_1$ is saved by IFF $_2$

NSC800

7

7-25

so that the complete state of the CPU just prior to the non-maskable interrupt may be restored. The method of restoring the status of IFF1 is through the execution of a Return Non-Maskable Interrupt (RETN) instruction. Since this instruction indicates that the non-maskable interrupt service routine is completed, the contents of IFF2 are now copied back into IFF1, so that the status of IFF1 just prior to the acceptance of the non-maskable interrupt will be automatically restored.

Figure 19 depicts the status of the flip flops during a sample series of interrupt instructions.

Interrupt Control Register. The interrupt control register (ICR) is a 4-bit, write only register that provides the programmer with a second level of maskable control over the four maskable interrupt inputs.

The ICR is internal to the NSC800 CPU, but is addressed through the I/O space at I/O address port X'BB. Each bit in the register controls a mask bit dedicated to each maskable interrupt, RSTA, RSTB, RSTC and INTR. For an interrupt request to be accepted on any of these inputs, the corresponding mask bit in the ICR must be set (= 1) and IFF1 and IFF2 must be set. This provides the programmer with control over individual interrupt inputs rather than just a system wide enable or disable.

Bit	Name	Function
0	1EI	Interrupt Enable for INTR
1	IEC	Interrupt Enable for RSTC
2	IEB	Interrupt Enable for RSTB
3	IEA	Interrupt Enable for RSTA

For example: In order to enable $\overline{\text{RSTB}}$, CPU interrupts must be enabled and IEB must be set.

At reset, IEI bit is set and other mask bits IEA, IEB, IEC are cleared. This maintains the software compatibility between NSC800 and Z80A.

Execution of an I/O block move instruction will not affect the state of the interrupt control bits. The only two instructions that will modify this write only register are OUT (C), r and OUT (N), A.

NSC800 SOFTWARE

10.0 Introduction

This chapter provides the reader with a detailed description of the NSC800 software. Each NSC800 instruction is described in terms of opcode, function, flags affected, timing, and addressing mode.

11.0 Addressing Modes

The following sections describe the addressing modes supported by the NSC800. Note that particular addressing modes are often restricted to certain types of instructions. Examples of instructions used in the particular addressing modes follow each mode description.

The 10 addressing modes and 158 instructions provide a flexible and powerful instruction set.

11.1 REGISTER

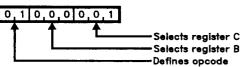

The most basic addressing mode is that which addresses data in the various CPU registers. In these cases, bits in the opcode select specific registers that are to be addressed by the instruction.

Example:

Instruction: Load register B from register C

Mnemonic: LD B,C

Opcode:

TL/C/5171-50

In this instruction, both the B and C registers are addressed by opcode bits.

11.2 IMPLIED

The implied addressing mode is an extension to the register addressing mode. In this mode, a specific register, the accumulator, is used in the execution of the instruction. In particular, arithmetic operations employ implied addressing, since the A register is assumed to be the destination register for the result without being specifically referenced in the opcode.

Example:

Instruction: Subtract the contents of register D from the Accumulator (A register)

Mnemonic: SUB D

Opcode:

In this instruction, the D register is addressed with register addressing, while the use of the A register is implied by the opcode.

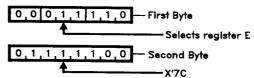

11.3 IMMEDIATE

The most straightforward way of introducing data to the CPU registers is via immediate addressing, where the data is contained in an additional byte of multi-byte instructions. Example:

Instruction: Load the E register with the constant value X'7C

Mnemonic: LD E,X'7C

Opcode:

TL/C/5171-52

In this instruction, the E register is addressed with register addressing, while the constant X'7C is immediate data in the second byte of the instruction.

11.4 IMMEDIATE EXTENDED

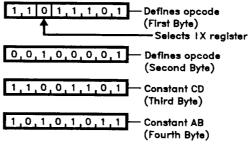

As immediate addressing allows 8 bits of data to be supplied by the operand, immediate extended addressing allows 16 bits of data to be supplied by the operand. These are in two additional bytes of the instruction.

Example

Instruction: Load the 16-bit IX register with the constant value X'ABCD.

Mnemonic: LD IX,X'ABCD

Opcode:

TL/C/5171-5

In this instruction, register addressing selects the IX register, while the 16-bit quanity X'ABCD is immediate data supplied as immediate extended format.

11.0 Addressing Modes (Continued)

11.5 DIRECT ADDRESSING

Direct addressing is the most straightforward way of addressing supplies a location in the memory space. Direct addressing, 16-bits of memory address information in two bytes of data as part of the instruction. The memory address could be either data, source of destination, or a location for program execution, as in program control instructions.

Example:

Instruction: Jump to location X'0377

Mnemonic: JP X'

Opcode:

This instruction loads the Program Counter (PC) is loaded with the constant in the second and third bytes of the instruction. The program counter contents are transferred via direct addressing.

11.6 REGISTER INDIRECT

Next to direct addressing, register indirect addressing provides the second most straightforward means of addressing memory. In register indirect addressing, a specified register pair contains the address of the desired memory location. The instruction references the register pair and the register contents define the memory location of the operand.

Example:

Instruction: Add the contents of memory location X'0254 to the A register. The HL register contains X'0254.

Mnemonic: ADD A,(HL)

Opcode

This instruction uses implied addressing of the A and HL registers and register indirect addressing to access the data pointed to by the HL register.

11.7 INDEXED

The most flexible mode of memory addressing is the indexed mode. This is similar to the register indirect mode of addressing because one of the two index registers (IX or IY) contains the base memory address. In addition, a byte of data included in the instruction acts as a displacement to the address in the index register.

Indexed addressing is particularly useful in dealing with lists of data.

Example:

Instruction: Increment the data in memory location X'1020.

The IY register contains X'1000.

Mnemonic: INC (

(IY + X'20)

0,0,1,1,0,1,0,0 opcode

0,0,1,0,0,0,0,0 Displacement to IY index register

(Third Byte)
TL/C/5171-54

Defines increment

The indexed addressing mode uses the contents of index registers IX or IY along with the displacement to form a pointer to memory.

11.8 RELATIVE

Certain instructions allow memory locations to be addressed as a position relative to the PC register. These instructions allow jumps to memory locations which are offsets around the program counter. The offset, together with the current program location, is determined through a displacement byte included in the instruction. The formation of this displacement byte is explained more fully in the "Instructions Set" section.

Example:

Instruction: Jump to a memory location 7 bytes beyond the current location.

Mnemonic: JR \$+7

Opcode:

The program will continue at a location seven locations past the current PC.

11.0 Addressing Modes (Continued)

11.9 MODIFIED PAGE ZERO

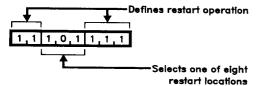

A subset of NSC800 instructions (the Restart instructions) provides a code-efficient single-byte instruction that allows CALLs to be performed to any one of eight dedicated locations in page zero (locations X'0000 to X'00FF). Normally, a CALL is a 3-byte instruction employing direct memory addressing.

Example:

Instruction: Perform a restart call to location X'0028.

Mnemonic: RST X'28

Opcode:

00H 08H 10H 18H 20H 28H 30H 38H 000 001 010 011 100 101 110 111 Program execution continues at location X'0028 after execution of a single-byte call employing modified page zero addressing.

11.10 BIT

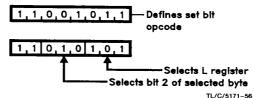

The NSC800 allows setting, resetting, and testing of individual bits in registers and memory data bytes.

Example:

Operation: Set bit 2 in the L register

Mnemonic: SET 2,L

Opcode:

Bit addressing allows the selection of bit 2 in the L register selected by register addressing.

12.0 Instruction Set

This section details the entire NSC800 instruction set in terms of

- Opcode
- Instruction
- Function
- Addressing Mode

The instructions are grouped in order under the following functional headings:

- 8-Bit Loads
- 16-Bit Loads
- 8-Bit Arithmetic
- 16-Bit Arithmetic
- Bit Set, Reset, and Test
- Rotate and Shift
- Exchanges
- Memory Block Moves and Searches
- Input/Output
- CPU Control
- Program Control

12.1 Instruction Set Index

Alphabetical Assembly Mnemonic	Operation
ADC A,m ₁	Add, with carry, memory location contents to Accumulator
ADC A,n	Add, with carry, immediate data n to Accumulator
ADC A,r	Add, with carry, register r contents to Accumulator
ADC HL,pp	Add, with carry, register pair pp to HL
ADD A,m ₁	Add memory location contents to Accumulator
ADD A,n	Add immediate data n to Accumulator
ADD A,r	Add register r contents to Accumulator
ADD HL,pp	Add register pair pp to HL
ADD IX,pp	Add register pair pp to IX
ADD IY,pp	Add register pair pp to IY
ADD ss,pp	Add register pair pp to contents of register pair ss
AND m ₁	Logical 'AND' memory contents to Accumulator
AND n	Logical 'AND' immediate data to Accumulator
AND r	Logical 'AND' register r contents to Accumulator
BIT b,m ₁	Test bit b of location m ₁
BIT b,r	Test bit b of register r
CALL cc,nn	Call subroutine at location nn if condition cc is true
CALL nn	Unconditional call to subroutine at location nn
CCF	Complement carry flag
CP m ₁	Compare memory contents with Accumulator
CP n	Compare immediate data n with Accumulator
CP r	Compare register r to contents with Accumulator
CPD	Compare location (HL) and Accumulator, decrement HL and BC
CPDR	Compare location (HL) and Accumulator, decrement HL and BC; repeat until BC $= 0$
CPI	Compare location (HL) and Accumulator, increment HL, decrement BC
CPIR	Compare location (HL) and Accumulator, increment HL, decrement BC; repeat until BC = 0
CPL	Complement Accumulator (1's complement)
DAA	Decimal adjust Accumulator
DEC m ₁	Decrement data in memory location m ₁
	Decrement register r contents
DEC r	

Alphabetical Assembly Mnemonic	Operation
DI	Disable interrupts
DJNZ,d	Decrement B and jump relative B \neq 0
El	Enable interrupts
EX (SP),ss	Exchange the location (SP) with register ss
EX AF,A'F'	Exchange the contents of AF and A'F'
EX DE,HL	Exchange the contents of DE and HL
EXX	Exchange the contents of BC, DE and HL with the contents of B'C, D'E' and H'L', respectively
HALT	Halt (wait for interrupt or reset)
IM 0	Set interrupt mode 0
IM 1	Set interrupt mode 1
IM 2	Set interrupt mode 2
IN A,(n)	Load Accumulator with input from device (n)
IN r,(C)	Load register r with input from device (C)
INC m ₁	Increment data in memory location m ₁
INC r	Increment register r
INC rr	Increment contents of register pair rr
IND	Load location (HL) with input from port (C), decrement HL and B
INDR	Load location (HL) with input from port (C), decrement HL and B; repeat until $B=0$
INI	Load location (HL) with input from port (C), increment HL, decrement B
INIR	Load location (HL) with input from port (C), increment HL, decrement B; repeat until $B=0$
JP cc,nn	Jump to location nn, if condition cc is true
JP nn	Unconditional jump to location nn
JP (ss)	Unconditional jump to location (ss)
JR d	Unconditional jump relative to PC + d
JR kk,d	Jump relative to PC + d, if kk true
LD A,I	Load Accumulator with register I contents
LD A,m ₂	Load Accumulator from location m ₂
LD A,R	Load Accumulator with register R contents
LD I,A	Load register I with Accumulator contents
LD m ₁ ,n	Load memory with immediate data n
LD m ₁ ,r	Load memory from register r
LD m ₂ ,A	Load memory from Accumulator
LD (nn),rr	Load memory location nn with register pair rr
LD r,m ₁	Load register r from memory
LD r,n	Load register with immediate data n
LD R,A	Load register R from Accumulator
LD r _d ,r _s	Load destination register r _d from source register r _s
LD rr,(nn)	Load register pair rr from memory location nn
LD rr,nn	Load register pair rr with immediate data nn
LD SP,ss	Load SP from register pair ss
LDD	Load location (DE) with location (HL), decrement DE, HL and BC
LDDR	Load location (DE) with location (HL), decrement DE, HL and BC; repeat until BC = 0
LDI LDIR	Load location (DE) with location (HL), increment DE and HL, decrement BC Load location (DE) with location (HL), increment DE and HL, decrement BC; repeat until BC $= 0$
NEG	Negate Accumulator (2's complement)
NOP	No operation

Alphabetical Assembly Mnemonic	Operation
OR m ₁	Logical 'OR' of memory location contents and accumulator
OR n	Logical 'OR' of immediate data n and Accumulator
OR r	Logical 'OR' of register r and Accumulator
OTDR	Load output port (C) with location (HL), decrement HL and B; repeat until B = 0
OTIR	Load output port (C) with location (HL), increment HL, decrement B; repeat until $B=0$
OUT (C),r	Load output port (C) with register r
OUT (n),A	Load output port (n) with Accumulator
OUTD	Load output port (C) with location (HL), decrement HL and B
OUTI	Load output port (C) with location (HL), increment HL, decrement B
POP qq	Load register pair qq with top of stack
PUSH qq	Load top of stack with register pair qq
DEC h m	Poset hit h of memory location my
RESb,m ₁	Reset bit b of memory location m ₁
RES b,r	Reset bit b of register r
RET	Unconditional return from subroutine
RET cc	Return from subroutine, if cc true
RETI	Unconditional return from interrupt
RETN	Unconditional return from non-maskable interrupt
RL m ₁	Rotate memory contents left through carry
RLr	Rotate register r left through carry
RLA	Rotate Accumulator left through carry
RLC m ₁	Rotate memory contents left circular
RLCr	Rotate register r left circular
RLCA	Rotate Accumulator left circular
RLD	Rotate digit left and right between Accumulator and memory (HL)
RR m ₁	Rotate memory contents right through carry
RRr	Rotate register r right through carry
RRA	Rotate Accumulator right through carry
RRC m ₁	Rotate memory contents right circular
RRCr	Rotate register r right circular
RRCA	Rotate Accumulator right circular
RRD	Rotate digit right and left between Accumulator and memory (HL)
RST P	Restart to location P
SBC A ₁ m ₁	Subtract, with carry, memory contents from Accumulator
SBC A,n	Subtract, with carry, immediate data n from Accumulator
SBC A,r	Subtract, with carry, register r from Accumulator
SBC HL,pp	Subtract, with carry, register morn Accommutation
SCF	Set carry flag
	Set bit b in memory location m ₁ contents
SET b,m1	Set bit b in register r
SET b,r	
SLA m ₁	Shift memory contents left, arithmetic
SLA r	Shift register r left, arithmetic
SRA m ₁	Shift memory contents right, arithmetic
SRA r	Shift register r right, arithmetic
SRL m ₁	Shift memory contents right, logical
SRLr	Shift register r right, logical
SUB m ₁	Subtract memory contents from Accumulator
SUB n	Subtract immediate data n from Accumulator
SUB r	Subtract register r from Accumulator
XOR m ₁	Exclusive 'OR' memory contents and Accumulator
XOR n	Exclusive 'OR' immediate data n and Accumulator
XOR r	Exclusive 'OR' register r and Accumulator

12.0 Instruction Set (Continued)

12.2 INSTRUCTION SET MNEMONIC NOTATION

In the following instruction set listing, the notations used are shown below.

- b: Designates one bit in a register or memory location. Bit address mode uses this indicator.
- cc: Designates condition codes used in conditional Jumps, Calls, and Return instruction; may be:
 - NZ = Non-Zero (Z flag = 0)
 - Z = Zero (Z flag = 1)
 - NC = Non-Carry (C flag = 0)
 - C = Carry (C flag = 1)
 - PO = Parity Odd or No Overflow (P/V=0)
 - PE = Parity Even or Overflow (P/V=1)
 - P = Positive (S = 0)
 - M = Negative (S = 1)
- d: Designates an 8-bit signed complement displacement. Relative or indexed address modes use this indicator.
- kk: Subset of cc condition codes used in conjunction with conditional relative jumps; may be NZ, Z, NC or C.
- $m_1: \quad \text{Designates (HL), (IX+d) or (IY+d). Register indirect} \\ \text{or indexed address modes use this indicator.}$
- m₂: Designates (BC), (DE) or (nn). Register indirect or direct address modes use this indicator.
- n: Any 8-bit binary number.
- nn: Any 16-bit binary number.
- Designates restart vectors and may be the hex values 0, 8, 10, 18, 20, 28, 30 or 38. Restart instructions employing the modified page zero addressing mode use this indicator.
- pp: Designates the BC, DE, SP or any 16-bit register used as a destination operand in 16-bit arithmetic operations employing the register address mode.
- qq: Designates BC, DE, HL, A, F, IX, or IY during operations employing register address mode.
- r: Designates A, B, C, D, E, H or L. Register addressing modes use this indicator.
- rr: Designates BC, DE, HL, SP, IX or IY. Register addressing modes use this indicator.
- ss: Designates HL, IX or IY. Register addressing modes use this indicator.
- X_L: Subscript L indicates the lower-order byte of a 16-bit register.
- X_H: Subscript H indicates the high-order byte of a 16-bit register.
- parentheses indicate the contents are considered a pointer address to a memory or I/O location.

12.3 ASSEMBLED OBJECT CODE NOTATION

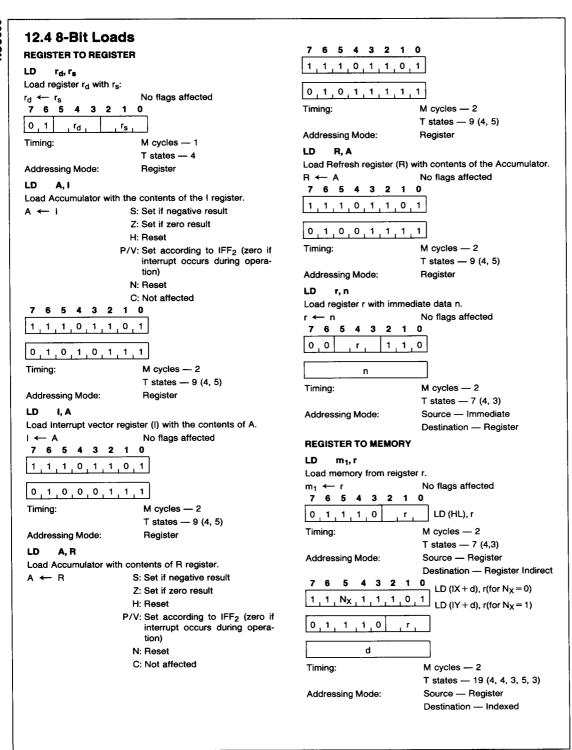

Register Codes:					
r	Register	rp	Register	rs	Register
000	В	00	BC	00	BC
001	С	01	DE	01	DE
010	D	10	HL	10	HL
011	E	11	SP	11	AF
100	н	pр	Register	qq	Register
101	L	00	BC	00	BC
111	Α	01	DE	01	DE
		10	IX	10	HL
		11	SP	11	AF

Conditi	ons Codes:	
CC	Mnemonic	Tre

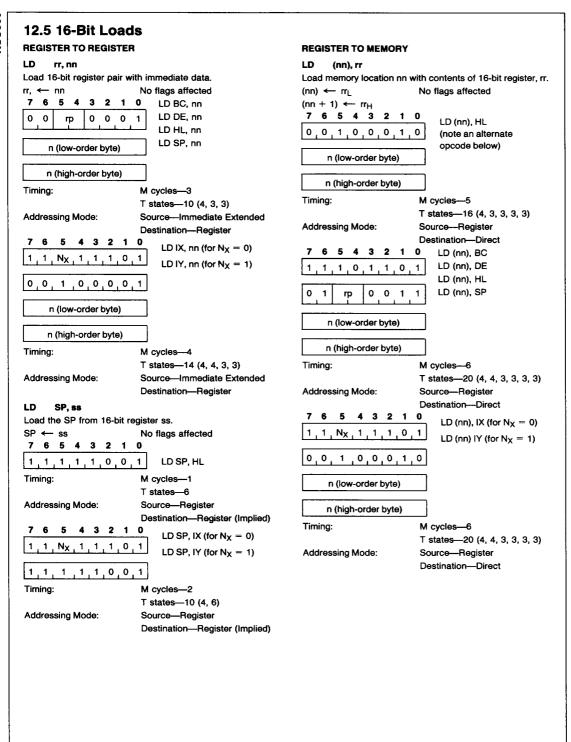

CC	Mnemonic	True Flag Condition
000	NZ	Z=0
001	Z	Z=1
010	NC	C=0
011	С	C=1
100	PO	P/V=0
101	PE	P/V = 1
110	Р	S=0
111	M	S = 1
kk	Mnemonic	True Flag Condition
00	NZ	Z=0
01	Z	Z=1
10	NC	C=0
11	С	C=1

Restart Addresses:

t	T
000	X'00
001	X'08
010	X'10
011	X'18
100	X'20
101	X'28
110	X'30
111	X'38

Destination-Implied

SBC A, r

Subtract contents of register r and the carry bit C from the Accumulator.

 $A \leftarrow A - r - CY$

S: Set if result is negative

Z: Set if result is zero

H: Set if borrow from bit 4 P/V: Set if result exceeds 8-bit 2's

complement range

N: Set

C: Set according to borrow

7 6 5 4 3 2 1 0 1,0,0,1,1

Timing:

M cycles-1

T states-4

Addressing Mode:

Source-Register

Destination-Implied

AND

Logically AND the contents of the r register and the Accumulator.

 $A \leftarrow A \wedge r$

S: Set if result is negative Z: Set if result is zero

H: Set

P/V: Set if result parity is even

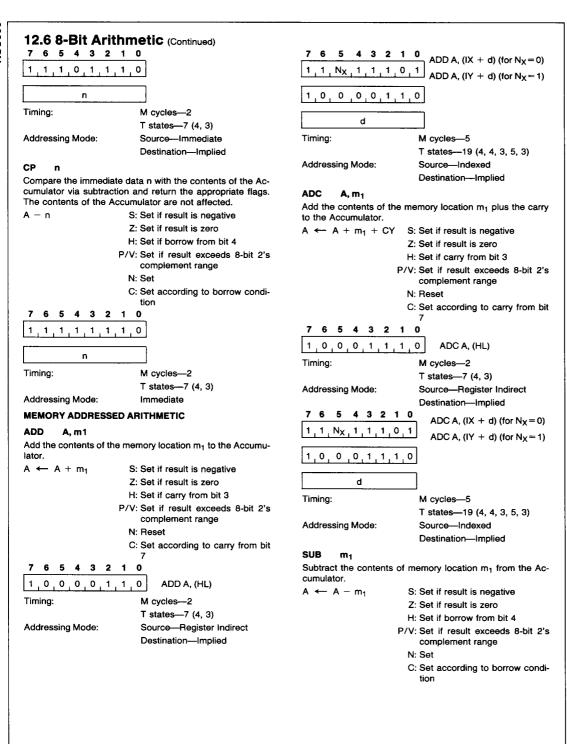

N: Reset

C: Reset

12.14 Program Control (Continued)

RETN

Unconditional return from non-maskable interrupt handling subroutine. Functionally similar to RET instruction, except interrupt enable state is restored to that prior to non-maskable interrupt.

 $PC_L \leftarrow (SP)$ $PC_H \leftarrow (SP + 1)$

No flags affected

SP ← SP + 2

 $IFF_1 \leftarrow IFF_2$ 7 6 5 4 3 2 1 0 1,1,1,0,1,1,0,1

0,1,0,0,0,1,0,1

Timing:

M cycles — 4

T states — 14 (4, 4, 3, 3)

Addressing Mode:

Register Indirect

RESTARTS

RST

The present contents of the PC are pushed onto the memory stack and the PC is loaded with dedicated program locations as determined by the specific restart executed.

 $(SP - 1) \leftarrow PC_H$ $(SP - 2) \leftarrow PC_L$

No flags affected

SP ← SP - 2

 $PC_{H} \leftarrow 0$ $PC_{L} \leftarrow P$

5 4 3 2 1 0

Timing:

T states --- 11 (5, 3, 3)

Addressing Mode:

Modified Page Zero

13.0 Data Acquisition System

A natural application for the NSC800 is one that requires remote operation. Since power consumption is low if the system consists of only CMOS components, the entire package can conceivably operate from only a battery power source. In the application described herein, the only source of power will be from a battery pack composed of a stacked array of NiCad batteries (see *Figure 20*).

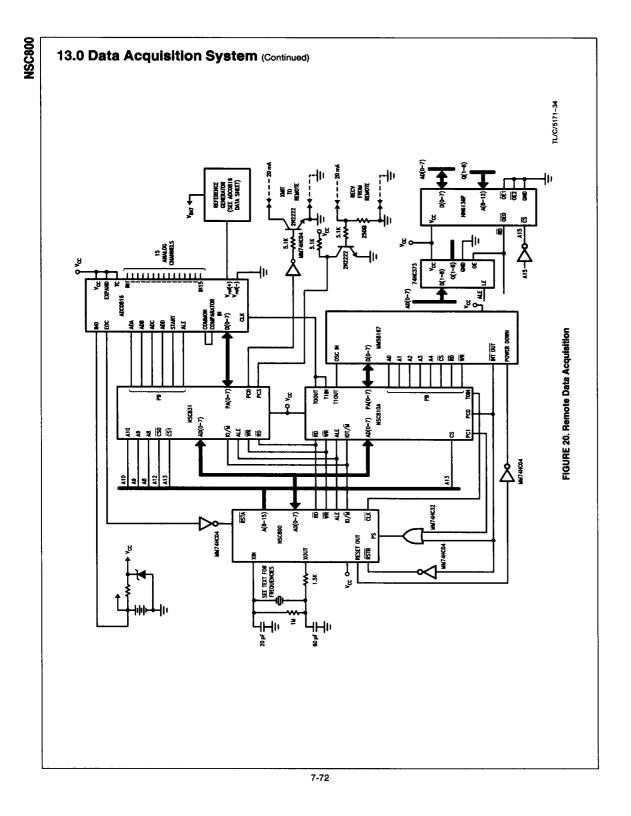

The application is that of a remote data acquisition system. Extensive use is made of some of the other LSI CMOS components manufactured by National: notably the ADC0816 and MM58167. The ADC0816 is a 16-channel analog-todigital converter which operates from a 5V source. The MM58167 is a microprocessor-compatible real-time clock (RTC). The schematic for this system is shown in Figure 20. All the necessary features of the system are contained in six integrated circuits: NSC800, NSC810A, NSC831, HN6136P, ADC0816, and MM58167. Some other small scale integration CMOS components are used for normal interface requirements. To reduce component count, linear selection techniques are used to generate chip selects for the NSC810A and NSC831. Included also is a current loop communication link to enable the remote system to transfer data collected to a host system.

In order to keep component count low and maximize effectiveness, many of the features of the NSC800 family have been utilized. The RAM section of the NSC810A is used as a data buffer to store intermediate measurements and as scratch pad memory for calculations. Both timers contained in the NSC810A are used to produce the clocks required by the A/D converter and the RTC. The Power-Save feature of the NSC800 makes it possible to reduce system power consumption when it is not necessary to collect any data. One of the analog input channels of the A/D is connected to the battery pack to enable the CPU to monitor its own voltage supply and notify the host that a battery change is needed. In operation, the NSC800 makes readings on various input conditions through the ADC0816. The type of devices connected to the A/D input depends on the nature of the remote environment. For example, the duties of the remote system might be to monitor temperature variations in a large building. In this case, the analog inputs would be connected to temperature transducers. If the system is situated in a process control environment, it might be monitoring fluid flow, temperatures, fluid levels, etc. In either case, operation would be necessary even if a power failure occurred, thus the need for battery operation or at least battery backup. At some fixed times or at some particular time durations, the system takes readings by selecting one of the analog input channels, commands the A/D to perform a conversion. reads the data, and then formats it for transmission; or, the system checks the readings against set points and transmits a warning if the set points are exceeded. With the addition of the RTC, the host need not command the remote system to take these readings each time it is necessary. The NSC800 could simply set up the RTC to interrupt it at a previously defined time and when the interrupt occurs, make the readings. The resultant values could be stored in the NSC810A for later correlation. In the example of temperature monitoring in a building, it might be desired to know the high and low temperatures for a 12-hour period. After compiling the information, the system could dump the data to the host over the communications link. Note from the schematic that the current for the communication link is supplied by the host to remove the constant current drain from the battery supply.

The required clocks for the two peripheral devices are generated by the two timers in the NSC810A. Through the use of various divisors, the master clock generated by the NSC800 is divided down to produce the clocks. Four examples are shown in the table following *Figure 20*.

All the crystal frequencies are standard frequencies. The various divisors listed are selected to produce, from the master clock frequency of the NSC800, an exact 32,768 Hz clock for the MM58167 and a clock within the operating range of the A/D converter.

The MM58167 is a programmable real-time clock that is microprocessor compatible. Its data format is BCD. It allows the system to program its interrupt register to produce an interrupt output either on a time of day match (which includes the day of the week, the date and month) and/or every month, week, day, hour, minute, second, or tenth of a second. With this capability added to the system, precise time of day measurements are possible without having the CPU do timekeeping. The interrupt output can be connected, through the use of one port bit of the NSC810A, to put the CPU in the power-save mode and reenable it at a preset time. The interrupt output is also connected to one of the hardware restart inputs (RSTB) to enable time duration measurements. This power-down mode of operation would not be possible if the NSC800 had the duties of timekeep-

13.0 Data Acquisition System (Continued)

ing. When in the power-save mode, the system power requirements are decreased by about 50%, thus extending battery life.

Communication with the peripheral devices (MM58167 and ADC0816) is accomplished through the I/O ports of the NSC810A and NSC831. The peripheral devices are not connected to the bus of the NSC800 as they are not directly compatible with a multiplexed bus structure. Therefore, additional components would be required to place them on the microprocessor bus. Writing data into the MM58167 is performed by first putting the desired data on Port A, followed by selecting the address of the internal register and applying the chip select through the use of Port B. A bit set and clear operation is performed to emulate a pulse on the bit of Port B connected to the WR input of the MM58167. For a read operation, the same sequence of operations is performed except that Port A is set for the input mode of operation and the RD line is pulsed. Similar techniques are used to read converted data from the A/D converter. When a conversion is desired, the CPU selects a channel and commands the ADC0816 to start a conversion. When the conversion is complete, the converter will produce an End-of-Conversion

signal which is connected to the $\overline{\mbox{RSTA}}$ interrupt input of the NSC800.

When operating, the system shown consumes about 125 mw. When in the power-save mode, power consumption is decreased to about 70 mw. If, as is likely, the system is in the power-save mode most of the time, battery life can be quite long depending on the amp-hour rating of the batteries incorporated into the system. For example, if the battery pack is rated at 5 amp-hours, the system should be able to operate for about 400-500 hours before a battery charge or change is required.

As shown in the schematic (refer to Figure 20), analog input IN0 is connected to the battery source. In this way, the CPU can monitor its own power source and notify the host that it needs a battery replacement or charge. Since the battery source shown is a stacked array of 7 NiCads producing 8.4V, the converter input is connected in the middle so that it can take a reading on two or three of the cells. Since NiCad batteries have a relatively constant voltage output until very nearly discharged, the CPU can sense that the "knee" of the discharge curve has been reached and notify the host.

Typical Timer Output Frequencies

Crystal Frequency	CPU Clock Output	Timer 0 Output	Timer 1 Output
2.097152 MHz	1.048576 MHz	262.144 kHz divisor = 4	32.768 kHz divisor = 8
3.276800 MHz	1.638400 MHz	327.680 kHz divisor = 5	32.768 kHz divisor = 10
4.194304 MHz	2.097152 MHz	262.144 kHz divisor = 8	32.768 kHz divisor = 8
4.915200 MHz	2.457600 MHz	491.520 kHz divisor = 5	32.768 kHz divisor = 15

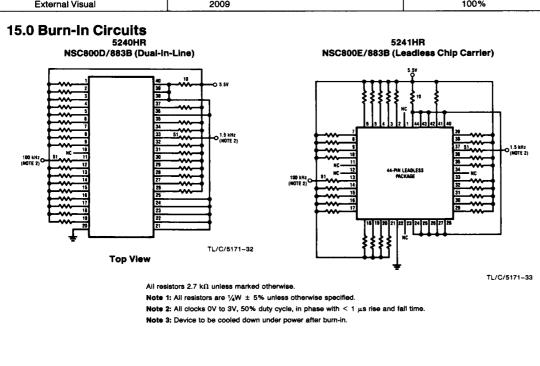

14.0 NSC800M/883B MIL-STD-833 Class C Screening

National Semiconductor offers the NSC800D and NSC800E with full class B screening per MIL-STD-883 for Military/ Aerospace programs requiring high reliability. In addition, this screening is available for all of the key NSC800 peripheral devices.

Electrical testing is performed in accordance with RESTS800X, which tests or guarantees all of the electrical performance characteristics of the NSC800 data sheet. A copy of the current revision of RETS800X is available upon request.
